> refer to - is it the matching coil or the loading coil? I only knew of
> mid-loaded bugcatchers.

A short whip can be fed at any point on the radiator.
In Cecil's case, I assume the coil was a true loading coil,
and not the matching coil. As per his numbers, the base
loaded was quite a bit better than the "tuner" loaded whip,
which was 12 db down from the center loaded bugcatcher.
In general, appx 3/4 the length of the whip from the base
will be the appx best location for the coil.
The higher the coil is, the better the current distribution.
But.. The higher the coil is, the more turns of wire you
need to tune. So there is a trade off of current distribution
vs coil loss due to the extra turns.
You could have the coil at 95% high, and have great
current distribution, but the losses of all the turns required
would eat you for lunch.
So... usually around 3/4 of the way up will be about the
optimum location. 1/2 way up is good, and a good compromise
between current distribution and coil losses.
For a given length whip, Reg Edwards "vertload" program
can be used to calculate the best location for the coil,
and having played with it, and using the real antennas to
compare, I think it is very close.
Also, it jives with the info and graphs used in the ARRL
antenna handbook on that subject.

On Fri, 4 Jun 2010 11:11:02 -0700 (PDT), walt <walt@w2du.com> wrote:

>Although Rp is definitely a factor in determining the value of load resistance RL, it is by no means the total source resistance RL, as others have insisted.

Hi Walt,

Do you have other Data to replace into your copy of Terman's equation? I got the impression you were satisfied with his work and his conclusions. Myself, I would say Terman's are suitable but incomplete and additional data wouldn't change anything as he presented a classic case.

Hemenway, Henry, and Caulton go miles beyond merely suggesting that there are partial derivative forms (you can choose to offer your own from Terman if you can find them), and they give the full treatment from soup to nuts in chapters outside of the one I have distributed.

As for the comparison of Rp to RL, yes, it is not complete and in fact although they closely agree, that is only a first cut. Refinement may go as far as 10s of percent shifts and with the accumulation of possible errors, that shift might still resolve to Rp = RL.

However, if Rp (or its distant cousin Rpd) slips in value away from RL, then the match is going to migrate away from the Conjugate basis Z match towards some other solution. I cannot see how it could be otherwise unless there were some undocumented and unmeasurable R (not real) were to combine to balance the books.

If there's a match, the Data and the numerous counter arguments to you seem to prefer an image basis Z match. I don't hold much confidence in that outcome either.

Sorry, I can't tell without seeing the EZNEC description file. If you'll
attach the .EZ file to an email message to me, I'll be glad to answer
your question. I wasn't able to get a radiation resistance that high at
that frequency for a 3 meter vertical of any diameter, so there's
something in the model which isn't immediately apparent.

And the same fundamental equations are used by modeling programs. The problem is that interaction between the antenna, an abbreviated ground system, and the Earth can modify the radiation resistance as well as adding loss resistance. You might try modeling a few short verticals with a few radials just above ground, and looking at the gain with various radial systems. You'll find that the gain change doesn't exactly correlate with the feedpoint resistance change when you assume a constant radiation resistance. This isn't a shortcoming of the modeling program, but a real effect. I doubt you'll find much about it in pre-computer age texts, though, because it's probably a very tough, or maybe impossible, manual calculation.

And yet....

It is generally accepted that power =3D volts times current (P=3DVI) and
that
power is energy flowing, so if the voltage or current is always 0,
there
must be no energy flowing.

The presence of voltage without current, or current without voltage is
an indication that energy is stored, not that energy is flowing.

So are you really prepared to give up on P=3DVI so that energy can be
flowing (i.e. there is power) when the voltage or current is zero?

Terman does seem to be extraordinarily careful with his language.

> The very term "standing waves" leads to endless Ham controversies about concept of "wave" word in our context.(wave as "a disturb that propagates" and wave as pattern-figure-graphics-representation of interference pattern of voltage/current measured along the TL). This "wave pattern" (is it correct to write "wavy" pattern?) do not carry any energy from one place to another on the TL it is not a "wave" in the other sense (transport phenomena). What do you think?

I tend to agree. Wave is an overloaded term and this leads to some of the confusion. There are some phenomena that transport energy which have a wavy nature. This does not mean that every thing with a wavy nature is transporting energy.

In particular, it does not mean that when there is a situation in which energy is not being transported (e.g. a zero on a transmission line), that just because the conditions on the line can be described by decomposing into two waves going in opposite directions, that these two waves are carrying energy.

Attempting to do this, and believing that these decomposed waves actually represent energy flows leads to having to answer questions like "where does the reflected energy go"? When I first started lurking in this group about a decade and half ago, the 'obvious' answer accepted by many was that it went in to the final and fried the tube. Many have moved beyond this simplicity, but some have not yet moved as far as they need to.

that is just another flaw in the 'standing wave' problem. since they
are not real waves that propagate and move energy the P=3DVI formula is
not correct. you must take the original traveling waves and study the
power and energy using them, from that you should see the proper
results.

My apologies for being insufficiently precise. Where ever I wrote
P=3DVI,
please substitute P(t)=3DV(t)I(t).

That is, the power (i.e. energy flow) at any instant in time is the
voltage at that time times the current at that time. If, for all time,
the current or voltage is 0, then so is the energy flow.

...Keith

Consider two equal valued resistors connected in series. Connect one end
of the pair to +12 volts, connect the other end of the pair to -12
volts. The voltage at the center is 0. There is certainly current
flowing. There clearly is power dissipated in the circuit.

>
> The presence of voltage without current, or current without voltage is

The above example has current but no voltage, There are no storage
elements, only resistors.

Inductance and capacitance are storage elements. You might find those in
a model of a transmission line, but not in this example.

I think you are looking to hard at a small part of the picture and not
seeing what else is going on.

Could you please explain why, if the same fundamental equations given
in antenna engineering textbooks and I.R.E. papers are used by
modeling programs, the results of their use do not always support each
other very well?

If it is accepted that the radiation resistance of a short monopole is
```

independent of the loss resistance in the loading coil and r-f ground either alone or together, then what is the basis for the variation in radiation resistance that you report?

BTW, the equations in the Carl Smith paper I referred to earlier in this thread produce a radiation resistance of 0.113 ohms for a 1.65 MHz, 9.84' (3-m) x 0.25" OD, base driven monopole -- which is not _hugely_ different than the values calculated by EZNEC.

RF

An excellent example. Let's draw it.

                      A
      +----\/\/\------+-----/\/\/\----+
      |                               |
     ---                              -
      -                              ---
      |               B               |
      +---------------+---------------+

Between A and B the voltage is zero. I contend that there is no energy
flowing from the left half of the circuit to the right half. To
demonstrate this, compute the energy contributed by the battery on the
left. It is equal to the energy consumed by the resistor on the left.
Similarly for the battery and resistor on the rigtht. No energy flows
across the plane A-B.

If you still disagree, what is the power flowing across A-B?
```

...Keith

> other very well?

I'm not aware of any cases where engineering textbooks and papers disagree with modeling programs. NEC, for example, has been very extensively tested against both theory and measurement. If there are cases where the programs seem to disagree with theory, it's very likely due to careless modeling resulting in a model which isn't the same as the textbook model. Can you cite an example of disagreement between computer model and textbook theory?

> If it is accepted that the radiation resistance of a short monopole is independent of the loss resistance in the loading coil and r-f ground either alone or together, then what is the basis for the variation in radiation resistance that you report?

It is indeed accepted that the radiation resistance of a monopole over a perfect ground of infinite extent has the characteristics you ascribe, and computer models show this independence as they should. (I haven't yet received your model which you feel seems to show differently.) But it's neither true nor "accepted" when the ground system is much less than perfect. The variation is due to interaction between the vertical and ground system, just as the radiation resistance of a VHF ground plane antenna changes as you bend the radials downward. Altering the number, length, depth, and orientation of radials has more of an effect than simply adding loss.

> BTW, the equations in the Carl Smith paper I referred to earlier in this thread produce a radiation resistance of 0.113 ohms for a 1.65 MHz, 9.84' (3-m) x 0.25" OD, base driven monopole -- which is not _hugely_ different than the values calculated by EZNEC.

EZNEC gives a result of 0.1095 ohm with 20 segments, converging to around 0.103 ohms with many more segments. Keep in mind that the model source position moves closer to the base as the number of segments increases.

The author's result is good. If you examine the paper carefully, I'm sure you'll find that the author had to make some assumptions and approximations to arrive at his equations -- the most fundamental equations can't be solved in closed form, and many, many papers and several books were written describing various approximations to calculate something as basic as the input impedance of an arbitrary length dipole. If you do some research, you'll find that the many different approximating methods all give slightly different results. The small disagreement in the cited paper is really a measure of how good his approximations were. Modeling programs have to use numerical methods which are limited by quantization, but they have the advantage of not needing the various approximation methods required for calculation by other means.

>I tend to agree. Wave is an overloaded term and this leads to some of
the confusion. There are some phenomena that transport energy which
have a wavy nature. This does not mean that every thing with a wavy
nature is transporting energy.

>In particular, it does not mean that when there is a situation in
which
energy is not being transported (e.g. a zero on a transmission line),
that just because the conditions on the line can be described by
decomposing into two waves going in opposite directions, that these
two waves are.

Also each pulse in the wave is carrying energy.

>Attempting to do this, and believing that these decomposed waves
actually represent energy flows leads to having to answer questions like
"where
does the reflected energy go"? When I first started lurking in this
group about a decade and half ago, the 'obvious' answer accepted by many was
that it went in to the final and fried the tube.

Members of this Group should know that in microwave oven are the standing waves, In the Manual is " when the amount of food is small, sharp points and sharp edges on metal objects can initiate a corona discharge, a "Saint Elmo's Fire," which behaves the same as a flame and can set fire to the food and the oven if allowed to continue for long. Aluminum foil can become a blow torch!"

Each pulse of the both waves travelling in the opposite direction is carrying energy. The energy cummulate and can destroy the tube or the oven.

>Many have moved beyond this simplicity, but some have not yet moved as far
>as they need to.

It is important to know that the standing waves are possible only in compressible medium.
"Maxwell's equations" are for the incompressible electricuty.

right, and this brings up another key error that a detailed look at
standing waves points out.  go look at one of the animations of
standing waves and you will note that in each cycle they go from tall
peaks to a flat line and then back to peaks. so if you use p=3Dvi  what
is the energy in the line when either field is zero from end to end?
if you answer zero, then where did it go?  it is obviously impossible
for the energy in the line to go to zero everywhere every half cycle
as that would require propagation faster than light, and some external
place for all that energy to dump to.  so calculating power that way
is worthless with standing waves.

The real die hard standing wave fanatics will look closer and realize
they can represent calculate power in each field separately and make
it slosh back and forth between electric fields and magnetic fields.
That representation may be interesting, but is nothing more than
studying the energy stored in a resonant LC circuit.  it doesn't go
anywhere, it just alternates between the electric and magnetic fields.

you need to go back to circuits 101 and retake the undergraduate lab intro where they teach you about measuring current and voltage. your basic problem statement above is malformed since you can not measure the voltage 'at the center'. voltages always have to be taken between two points.

now if you REALLY want to be confused, ignore circuits 101 and draw any circuit with as many components in it as you want as long as there is only ONE loop. so connect AC or DC sources, inductors, capacitors, resistors, around in a circle. start measuring voltage across each

one as you go around the circle and add them up. the result will
ALWAYS be zero. (go read about Kirchhoff's laws, here is one
reference http://www.bowest.com.au/library/theorems.html).

Note that of course these do not apply to transmission line problems
or antennas.

> is the energy in the line when either field is zero from end to end?

We need to carefully understand the meaning of the words. Power is energy that is moving; the SI unit is the watt or joule per second. The unit for energy is the joule.

When the voltage or current is zero everywhere, there is no power, that is, no energy is moving. The energy is stored on the line where it happens to be. As the voltage or current rises again from zero, the energy is now moving in the direction opposite to the direction it was moving before the line was zero everywhere. At a point where the voltage or current is always zero, no energy moves. The energy sloshes back and forth between the points in the line that it never crosses.

> it just alternates between the electric and magnetic fields

This is true, but the energy also changes location as it does this, leading to energy flow (or power), but the energy does not cross any point where the voltage or current is always zero.

When the current everywhere is zero, no energy is flowing, and the energy is stored as voltage in the capacitance of the line. And those voltages are at maximum and will soon begin to decrease as the energy begins to flow the other way.

Similarly, when the voltage is zero everywhere, the energy is stored as current in the inductance of the line.

...Keith

Funny, Keith understood exactly what I meant. I find it hard to believe
you couldn't figure out the implied reference point. (I.e., what the
supplies were connected to.)

Since you include AC sources, the voltages must all be measured at the
same time. Circuits 101 should tell you that.

Which was part of my point, picking at some details may not lead you to
the proper view of what is going on.

>yet received your model which you feel seems to show differently.)

The .EZ files for Case 1 and Case 2 were emailed to you this morning.

I had also modeled this short monopole system earlier with basically
the same parameters, using another NEC-2 program (results follow):

```
NEC-Win Plus+ OUTPUT DATA
-------------------------
C:\Program Files\NEC-WIN\RJF Antenna Files\Case 1.NOU

FREQUENCY=3D 1.6500E+00 MHZ
WAVELENGTH=3D 1.8170E+02 METERS

VSWR
----
Tag: 1, Segment: 1
Input Impedance:
   Real(Z) =3D 0.1127   Imag(Z)  =3D -0.0653

C:\Program Files\NEC-WIN\RJF Antenna Files\Case 2.NOU

FREQUENCY=3D 1.6500E+00 MHZ
WAVELENGTH=3D 1.8170E+02 METERS

VSWR
----
Tag: 1, Segment: 1
Input Impedance:
   Real(Z) =3D 25.1127   Imag(Z)  =3D -0.0653
```

This NEC study produced identical values of radiation resistance and
input reactance for the same conditions, whereas the EZNEC
calculations, while fairly close, varied from each other. I suppose
this small difference is related to small differences in the
parameters used for the models.

The values of radiation resistance (0.1127 ohms) calculated by NEC-WIN
+ are a very close match to the 0.113 ohms calculated using the
equation in the Carl E. Smith paper.

Below are the two NEC input files from the NEC-WIN+ study, if anybody wants to load the values into another NEC program to experiment. The only difference between them is in the load (LD) definition.

```

Excuse me!!
Would you stop for a moment?!
O...man...Haven't you thought-one day- about yourself ?
Who has made it?
Have you seen a design which hasn't a designer ?!
Have you seen a wonderful,delicate work without a worker ?!
It's you and the whole universe!..
Who has made them all ?!!
You know who ?.. It's "ALLAH",prise be to him.
Just think for a moment.
How are you going to be after death ?!
Can you believe that this exact system of the universe and all of
these great creation will end in in nothing...just after death!
Have you thought, for a second, How to save your soul from Allah's
punishment?!
Haven't you thought about what is the right religion?!
Read ... and think deeply before you answer..
It is religion of Islam.
It is the religion that Mohammad-peace upon him- the last prophet, had
been sent by.
It is the religion that the right Bible- which is not distorted-has
preached.
Just have a look at The Bible of (Bernaba).
Don't be emstional.
Be rational and judge..
Just look..listen...compare..and then judge and say your word.
We advise you visiting :

Keith, you keep leaving out the word "net". If the current on each side of a zero-current point is not zero, all that zero current measurement means is there is equal energy flowing in both directions so there is no *net* energy flow. The fact that Maxwell's equations cannot be used on your condition of interest should be a clue that something is wrong with your concepts and/or logic. You are essentially saying that there is no traffic on the Golden Gate Bridge because the north and south traffic averages out to zero. It is a faulty concept. That zero net traffic keeps on wearing out the roadway.

> flowing (i.e. there is power) when the voltage or current is zero?

Your equation is for DC power. The equation for net AC power is P=3DV*I*cos(theta). Since, for a pure standing wave, the net voltage is always 90 degrees out of phase with the net current, the net power at ALL points is zero, not just at the I=3D0 point. cos(theta) is ALWAYS zero for a pure standing wave whether I=3D0 or not - so your argument is moot. For a pure standing wave, P =3D V*I*cos(theta) is ALWAYS zero. I or V going to zero cannot make it more zero than it already is.

For a pure standing wave, the forward Poynting vector and the reflected Poynting vector sum to zero AT ALL POINTS.

You left out the word "net" again. Indeed, there is zero *net* energy flow in a pure standing wave. It is technically not a wave because it doesn't transfer energy and momentum. The forward and reflected Poynting vectors can be of any magnitude. They are just equal in magnitude whatever that magnitude might be.

Keith, could you refresh my memory on those instantaneous power equations that you once published. Given a forward wave and a reflected wave, what was your equation for instantaneous power? None of my references consider EM standing wave instantaneous power to be important enough to present a mathematical treatment of the subject.

Just a nit - there is a frequency at which the voltages will begin not summing to zero. That's when it is time to discard the lumped-circuit model and go to the distributed network model or Maxwell's equations.

On Jun 5, 7:08=A0am, Keith Dysart <keith.dys...@gmail.com> wrote:
> We need to carefully understand the meaning of the words. Power is
> energy that is moving;

Correction, it must be moving past a point, not just moving laterally from an inductance to a capacitance and back. There is zero net average power anywhere on a wire containing a pure standing wave. Therefore, there is zero net energy flow anywhere on a pure standing wave, not just at the zero current and zero voltage points. The average power in a pure standing wave is zero whether the current or voltage is zero or not. What is important for power is the phase angle between the net current phasor and the net voltage phasor which is always 90 degrees for a pure standing wave. The fact that *power is a scalar with no negative values* and *the average power is zero*, leads one to conclude that instantaneous power is just a mathematical curiosity. Exactly how can the instantaneous power average out to zero average power if there are no negative values of instantaneous power? Seems to me to be one of those numerous "undefined" or "indeterminate" conditions that unfortunately exists in mathematics. When you solve a quadratic equation for a resistance and get plus or minus 100 ohms, do you actually start searching for a -100 ohm resistor? Then why, when you know the average power is zero, do you ask us to go searching for some negative instantaneous power that doesn't exist?

Since power is energy flow *per unit time*, I don't see how power calculated over zero unit time can be anything more than a mathematical curiosity existing in human brains - and unrelated to reality. When one integrates instantaneous standing wave power over one cycle and gets anything except zero, one needs to recognize the error or one's ways.

Hi. =A1Good evening (here) to all..!

> We need to carefully understand the meaning of the words. Power is
> energy that is moving;

Since the energy can be dissipated also transmitted, If we talk in
power FLUX terms (instead power only), I think the issue it would be a
little more understandable because surfaces may have associated
vectors (with "power moving" I believe you are thinking about power
crossing an imaginary surface)

(Note: when I spoke about "unidimensional" nature of a TL space I am pointing to "degrees of freedom" of energy flux circumscribed to its physical path, of course).

For the sake of example we could imaginate a coaxial TL provided with a resistive inner conductor and perfectly conductive outer one. On such TL perhaps we could clearly visualize power flux vector (Poynting vector) "slanted" towards inner conductor to "see" -through simple vectorial decomposition on (over?) the inner wire and pependicular to it directions both =3D> transmission and dissipative nature of phenomenom.
At the same time I believe will be also more ease to account for net power FLUX of opposite directions traveling waves and do not confuse with net power being zero, leading us to the idea of zero energy stored in a ideal resonant TL. Note: In my last mensage I forget to clear that with "resonant line" I was speaking about a section of TL with its ends open or shorted (or a mix) to force a "chemically pure" standing wave :>)

I believe we always must escape from words as "real" or "true" (outside of safe environments such mathematics or digital logic), because "she" easily leads us to the Holy Inquisition dangers :>) Let us the Wave word to be free for jointing with standing, sine, hand, etc, etc. and do we make efforts to understand its conceptual meaning on each context :>)

sorry, you are of course correct that there could still be energy
stored in the fields when the instantaneous power is zero... wrote
that before having enough caffeine this morning.

agreed in general.  the initial premise was a couple resistors and
batteries... this is strictly true only for instantaneous voltages
across lumped components.

I recently was able to use a crimp on tool for F connectors for RG-6 quad shield coax. To make sure everyone understands, I am in Israel, and RG-6 quad shield coax is cheap and easy to find.

Any other coax is almost impossible to find. Pl-259 connectors, called "UHF" connectors here are rare items. I can get them locally, but I have to special order them and they are expensive. Since I can not see them before I order them, I am as likely to get nickle plated ones with phenolic insulation as I am to get any other kind, and once ordered are not returnable.

BNC to PL-259 adaptors, are easy to get, and can be ordered from a reliable local souce for a relatively small price. The same with N to PL-259.

Looking around at the crimp-on F connectors before I ordered them, I found that you can get crimp on BNC connectors for RG-6 quad shield coax.

Here's my questions, Note when I say crimp-on, I mean the ones that crimp from the rear, like commerical F connectors, not the ones that crimp around the plug. I have never been able to get any of them to "fit right":

1. Can I connect a 75ohm BNC plug (which is a different size) to a 50oHm BNC socket?

2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad shield? I know there are variations, but most are similar in size.

3. Are there crimp on N connectors that would fit the RG6 quad shield coax? More likely due to the size a crimp on center element that screws into the plug body?

4. Are there crimp on PL-259 connectors?

Thanks in advance,

Geoff.

There is such a thing as a 75 ohm BNC connector, but you are almost certainly looking at 50 ohm connectors designed for use on 75 ohm cable. My recollection is that the 75 ohm connectors are incompatible with the 50 ohm connectors, and in some combinations will spread the female inner part.

>
> 2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad
> shield?
>   I know there are variations, but most are similar in size.

Yes, see http://www.vk1od.net/transmissionline/RG6/index.htm .

>
> 3. Are there crimp on N connectors that would fit the RG6 quad shield
> coax?

I haven't seen any. I use BNC compression connectors on the RG6, then BNC/N adapters to connect to the antenna N connector. Works fine, all waterproof.

>   More likely due to the size a crimp on center element that screws
>   into the plug body?
>
> 4. Are there crimp on PL-259 connectors?

Yes. They have most of the disadvantages of the PL-259.

If you are of the view that everything that comes out of China, leave now.

I buy N, BNC, UHF, etc connectors that are of Chinese original that are economical and excellent quality. But... you have to be picky, price is not a good indicator of quality.

There is also a prejudice against RG6. Again, quality varies, and you need to inspect carefully and test product that you might use.

Not left out. No need to mention since this is the only energy
involved.

> Indeed, there is zero *net* energy
> flow in a pure standing wave. It is technically not a wave because it
> doesn't transfer energy and momentum.

Certainly a standing wave is not a wave that transfers energy.

> Keith, could you refresh my memory on those instantaneous power equations that you once published. Given a forward wave and a reflected wave, what was your equation for instantaneous power?

Choose a point on the line. Measure the instantaneous voltage and current at that point. Multiply them together. You have the instantaneous energy flow at that point and time. Integrate over a full cycle (assuming a repetitive signal), divide by the period and you have the average energy flow.

> None
> of my references consider EM standing wave instantaneous power to be important enough to present a mathematical treatment of the subject.

Definitely not of interest for standing waves (which everyone agrees are not really waves), but any decent text will derive Pavg=3DVrms*Irms*cos(theta) for sinusoids by doing exactly the steps I mention above.

You are welcome.

...Keith

> from an inductance to a capacitance and back.

Yes, indeed. And so it does. At any point where the voltage or current
is not always 0, energy moves back and forth. This can be readily seen
by computing P(t)=3DV(t)*I(t) at such a point. P(t) will be a sinusoid
describing the energy flow in the time domain.

> There is zero net
> average power anywhere on a wire containing a pure standing wave.

Yes, but to understand the details, time domain analysis is a great
asset. You need to move away from just averages to understand what
is going on.

> Therefore, there is zero net energy flow anywhere on a pure standing

True, but the instantaneous power is not.

On the contrary. It is computable and measurable.

> Exactly how can the instantaneous power average out to zero
```

> average power if there are no negative values of instantaneous power?

There are indeed negative values. These occur when the energy is flowing
in the other direction, i.e. the direction opposite to that represented
by positive values of power.

In P(t)=3DV(t)I(t), when V(t) and I(t) have different signs, P(t) is negative.

Ahhhhh, but it does. One does not need to search far if one starts with
a time domain analysis.

> Since power is energy flow *per unit time*, I don't see how power
> calculated over zero unit time can be anything more than a
> mathematical curiosity existing in human brains - and unrelated to

Well, this is the basis for calculus...
- instantaneous velocity
- instantaneous acceleration
- instantaneous jerk
- instantaneous voltage
- instantaneous rate of change of voltage
- instantaneous power

All are well understood concepts... and related to reality.

> When one integrates instantaneous standing wave power over
> one cycle and gets anything except zero, one needs to recognize the
> error or one's ways.

In a 'pure standing wave', such integration does result in zero, as
expected. But looking at the time domain details helps reveal the
fine grained behaviour that is obscured when only averages are
considered.

My apologies for being too terse for you. Please use P(t)=3DV(t)I(t)

> Your equation is for DC power. The equation for net AC power is
> P=3DV*I*cos(theta).

This simplified form works for sinusoids. It is derived from
P(t)=3DV(t)I(t),
but loses information since the result is just the average value.

> Since, for a pure standing wave, the net voltage is
> always 90 degrees out of phase with the net current, the net power at

> zero for a pure standing wave whether I=3D0 or not

Well so it appears when you use the simplified form, but if you use
P(t)=3DV(t)I(t), that is, do a bit of time domain analysis, one finds
that energy is moving back in forth within the line. It only does
not cross those points where V or I is always 0.

> - so your argument is moot.
> For a pure standing wave, P =3D V*I*cos(theta) is ALWAYS zero. I
> or V going to zero cannot make it more zero than it already is.

The difference will be easy to see if you analyze in the time domain
rather than just using the averages.

I expect to put some more things on my page
especially the model that I am honing now.
Now I have a 8 inch dia coil about 4 inches high relatively close
wound. Inside is the counter wound coil connected to the other coil to
make a closed circuit. It is placed on a perfect ground in leau of a
reflector. What I have done is balanced the inductance with the
capacitance, as you move around in frequency it will always be close
to resistive because of the balancing I have done.
It takes a while for the program to work from near
near resistance (.01 ohms) and I have now reached 11 ohms for 16.5 dbi
gain where the lower resistance gave me about 30 dbi
The resistance values are wave like as is the variation in gain per
cycle. Field shape so far varies from elliptical to something like the
double. zepp. My intention is to plot up to 20 ohms and that will take
several times longer than that taken already. The model has about a
dozen sections per
winding and I am pretty much limited to 10 segments per section. All
very interesting because I am following the idea of canceling all
lumped loads in line with Maxwells laws that deals only with
distributed loads. Frequency range covered up to now is 685 to 1200Mhz
With this amount of information you can start laughing now well
before I put it up

Thanks,

The ad I saw said they were 75 ohm. If they really are 50 ohm connectors
for 75 ohm cable, so much the better. Without buying them, I have no way
to tell, and it's awfully expensive to buy one or two.

Shipping from the US to here runs between $20 (USPS) and $50 (FEDEX/DHL/UPS)
for anything. I was going to buy $10 worth of soldering iron tips from
Farnell, and they wanted a flat rate of $35 to ship them. :-(

As in everything in life. :-)

Geoff.

On Sat, 5 Jun 2010 21:49:32 +0000 (UTC), "Geoffrey S. Mendelson" <gsm@cable.mendelson.com> wrote:

>I recently was able to use a crimp on tool for F connectors for RG-6 quad shield coax.

Hopefully, it was a "push-on" tool and connector <http://www.arrisistore.com/digicon/Digicon-F-Connector-Installation-Guide.pdf> not the piece of junk with the small crimped ring.

>To make sure everyone understands, I am in Israel, and RG-6 quad shield coax is cheap and easy to find.

There's quality RG-6a/u and junk. On the left coast of the USA, we have both in copious quantities. I obtain mine directly from a satellite DTV install company, so the quality is more towards quality than junk.

>Pl-259 connectors, called "UHF" connectors here are rare items.

Be thankful. I find them to be a necessary evil as most ham radios require them. Meanwhile, commercial radios are moving away from UHF and toward other connectors, such as Type-N, BNC, TNC, Mini-UHF, and SMA. However, Comerica base antennas remain UHF or Type-N.

>BNC to PL-259 adaptors, are easy to get, and can be ordered from a reliable local souce for a relatively small price. The same with N to PL-259.

That's what I do. Most of my cables are NOT terminated with UHF connectors. If I need to go to UHF, I use an adapter.

>Looking around at the crimp-on F connectors before I ordered them, I found that you can get crimp on BNC connectors for RG-6 quad shield coax.

Yes, they work. I use quite a bit of RG-6a/u and prefer to have everything terminated by the same connector, which is the CATV standard F connector. If I need BNC, I use an adapter.

>Here's my questions, Note when I say crimp-on, I mean the ones that crimp from the rear, like commerical F connectors, not the ones that crimp around the plug. I have never been able to get any of them to "fit right":

Agreed. The good ones are "push on" F connectors.

>1. Can I connect a 75ohm BNC plug (which is a different size) to a 50oHm BNC socket?

There are such things as real 75 ohm BNC plugs and jacks. They're easy to recognize because they lack the PTFE dielectric. The 75 ohm

connectors will mate properly with the 50 ohm connectors. There is little risk of VSWR problems from using 50 ohm connectors on RG-6a/u.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>
Basically, any small loss from VSWR is compensated by the lower loss per meter of RG-6a/u as compared to RG-58a/u. Methinks you're safe using all 50 ohm connectors.[1]

>2. Are there crimp on 50 ohm BNC plugs which will work with RG6 quad shield?
>   I know there are variations, but most are similar in size.

They're nearly identical in dimensions. The 50 ohm variety have some manner of PTFE dielectric. The 75 ohm variety use a plastic disk and no dielectric.
<http://www.amphenolconnex.com/products/bnc.asp>
   "50 ohm and 75 ohm connectors are intermateable to ensure
   non-destructive mating"
The catch is that there's no guarantee that this is true between different manufacturers. I've blundered across mutations and variations that are NOT interchangeable.

>3. Are there crimp on N connectors that would fit the RG6 quad shield coax?
>   More likely due to the size a crimp on center element that screws into the
>   plug body?

Probably, but I wouldn't use one. Just terminate in an F connector, and use an F to N adapter. The price will probably be the same or less. However, if you must go direct, any N connector that will fit RG-59a/u will usually work with RG-6a/u. The problem is that depending on the number of shields in the RG-6a/u, the outer diameter will vary, making the diameter of the crimp ring an issue. Doing this is risky and may result in a non-fitting connector. I would use an adapter, which will always work.

>4. Are there crimp on PL-259 connectors?

Also probably, but again, methinks you're better off with an F connector and an adapter.

[1] I just counted 7 assorted coaxial cables going between my roof and various RF devices in my house. All but one are 75 ohm RG-6a/u. Some are double shielded, while others are quad shielded. The connectors are slightly different. All the HF and VHF/UHF antennas use 75 ohm coax. The one 50 ohm LMR-400 run is for the 900MHz antenna.

Thanks,

Yes, but mine looks more like a nut cracker, however it works the same
way.

> Be thankful. I find them to be a necessary evil as most ham radios
> require them. Meanwhile, commercial radios are moving away from UHF

Me too. Since all of the ham radios I have were either brought from the
US in 1996 when I moved here, or even older ones brought here, they use
Pl-259's or in one case an RCA jack (Drake SP-R4) for the antenna.

TV sets still use the Belling-Lee plugs (called PAL connectors in the US)
and so do VCRs. Everything else uses F connectors (cable TV, Satellite TV)
although RF outputs to TV sets have gone the way of the VCR.

DVB is just starting here and the tuners use Belling-Lee connectors. F
to Belling-Lee adaptors are common here, and even in the US, where Radio
Shack sells them.

> That's what I do. Most of my cables are NOT terminated with UHF

OK, So where do you get your adaptors?

> Agreed. The good ones are "push on" F connectors.

I gave up about 10 years ago and used the cheap screw on ones because they gave me a better fit than the crimp "around" types. The push on ones are a lot better.

That's not an issue, 900mHz is not a ham band here, and 1.gHz too short range to consider using. I think there is one 1.2gHz repeater in the country, and I can't hit the co-located 2m repeater anyway.

Geoff.

just did a check at 3 Ghz. 20 dbi at 5 ohm resistive
so I may not get to 20- ohm resistive So after I get a reasonable
graph I will have to modify the model
to see if I can increase the resistance spam.
Note that the metallic resistance calculated is to gauge losses and is
not the source impeadance

My guess(tm) is that they are less expensive than oddities such as an N-connector for RG-6a/u. They also have the advantage of being reusable. When you destroy your coax cable, just unscrew the adapters and use a new F connector.

I sometimes have to make my own adapters. It's not because the adapter is unavailable or hard to find. It's because the accumulated length of the connectors and adapters can get quite long. There are also mechanical considerations, where an N to SMA adapter will surely break at the SMA when the heavy cable is bent. For SMA and Mini-UHF adapters, I sometimes use short pigtails to act as a strain relief.

>OK, So where do you get your adaptors?

It varies. Once a year, I got to one local hamfest and stock up. I like to see the connectors to make sure they're not junk. I typically buy about $150 worth every year. Much of it disappears during Field Day. The problem is that most of this stuff is nickel plated. Nickel is fine for systems which are not potentially affected by intermodulation issues. Therefore, I'll use them at home, Field Day, other hams stations, and my mobile. I won't use them for repeaters, mountain top sites, and microwave links.
<http://www.amphenolrf.com/simple/PIM%20Paper.pdf>
<http://www.repeater-builder.com/antenna/pdf/andrew-braid-over-foil-imd.pdf>
<http://www.repeater-builder.com/antenna/pdf/recommended-coax-and-connectors-for-iden.pdf>

For repeaters, I use silver plated connectors, when I can get them. Gold plating is an option, but under the gold is a layer of nickel, which worries me a little (most of the RF flows on the surface). Tin plate also works. I buy most of my connectors from RF Industries:
<http://www.rfcoaxconnectors.com>
Their mix is really bizarre. They offer Nickel, Tin, Silver and Gold plating, but not in every type of connector. For example, F adapters are available only in Nickel or Gold, while UHF connector are only available in Nickel and Silver. Trying to avoid dissimilar metals is difficult.

Other sources are eBay, various online dealers, the local electronics store:
<http://www.santacruzelectronics.com>
the local cable company, and the local DTV satellite installation company. The latter are my best sources of RG-6a/u and F connectors. I once obtained a free bucket full of filthy connectors that someone had left in the rain. Rather than clean them, they went to me, instead of the recyclers. There were literally hundreds of F connectors in the bucket.

If you're working on the HF and VHF bands, you can probably just solder two connectors together to make an adapter. I have a bunch of BNC to UHF adapter I made this way. The BNC panel jack fits nicely into the PL-259 connector. The losses are not signifigant, even at microwave (2.4GHz) frequencies:
<http://802.11junk.com/jeffl/antennas/connector-loss/>
I've done 8 ft chains of adapters with similar results.

I don't know what to suggest. It sounds like getting someone in Europe to throw together a collection of connectors for you seems easier than importing them one at a time.

Actually Miguel, I want you to note how a simple semantic misunderstanding can lead to false assumptions that propagate to: 1. false assertions, 2. accusations, and 3. character assignation. I said earlier that I was referring only to coherent/collimated waves that are TRAVELING IN THE SAME DIRECTION. K1TTT apparently missed that caveat and was simply confused about what I had said. Based on that false assumption, Richard, as usual, jumped on the "kill the messenger" bandwagon. He doesn't seem to realize that he has to prove quantum electrodynamics to be wrong to prove me wrong, a feat that no mortal has yet accomplished.

```

> No, no, no. I am NOT talking about forward and reflected waves moving in opposite directions. I am talking about two coherent, collimated waves *MOVING IN THE SAME DIRECTION* in an RF transmission line away from an impedance discontinuity - either two waves moving forward toward the load or two waves moving backwards in the opposite direction toward the source. Such multiple wavefronts occur at impedance discontinuities because of multiple reflections.
>
> Forward and reflected waves (waves moving in opposite directions in a constant Z0 environment) do NOT interact. At an impedance discontinuity, the component reflections and transmissive waves do interact if they are coherent, collimated, and MOVING IN THE SAME DIRECTION.
> --

add another condition and i might buy it... their polarization must be the same... if you satisfy ALL those conditions then i believe you would not be able to separate the waves and you could combine their amplitudes. but that still doesn't mean they are interacting, just that their fields always happen to be aligned... now if you are an engineer like i am and deal with macroscopic processes i would consider it perfectly logical to add the fields in a linear medium and carry on with a single wave in each direction created by an infinite series of reflections... HOWEVER, if i switch my hat to the scientist part of my job title and i was working in photons I would come to a point where it would be impossible to divide the last photon and things would fall apart.... fortunately the ham/engineer side usually outvotes the scientist part and i take the infinite summation and call it a day.

what does happen to that last photon in the infinite series of smaller
and smaller reflections between discontinuities??

If they are coherent, their polarization must necessarily be the same
at the same point at the same time. I specified that they are
coherent, collimated, and traveling in the same direction. I'm not
omniscient so if that's not enough boundary conditions, please
enlighten me.

It doesn't matter. At HF wavelengths, the last photon is not going to
have an appreciable effect (but maybe at gamma-ray wavelengths). The
collapse of the probability function indicates that if one runs a
large number of trials, n% of those very last photons will be

reflected and (100-n%) of them will be absorbed. That probability function has never been proven to be wrong.

I have no idea why an otherwise knowledgeable individual could be argumentative concerning this subject.

Walt, W2DU wrote:
"Rp is a non-dissipative resistance, not a tesisTOR with physical characteristics."

To nit pick a little, I think some dissipative resistance is found in the output impedance of a Class C amplifier when you average over an RF cycle.

Although rp (dynamic plate resistance) is defined as the change in plate voltage divided by the change in plate current when an increment of plate voltage produces an incremantal change in plate current, plate resistance goes down as plate current goes up.

Rp can be very low but not zero when a tube biased beyond its cut-off is pulsed on heavily duting the RF cycle. In saturated conduction the voltage drop actoss the tube can be very low and any change in plate voltage would result in insignificant change in plate current.

When a Class C amplifier is switched into heavy conduction by its grid, its DC resistance is low and its power suppy may be low in resistance too. During the conduction part of the RF cycle, the impedance looking back into the amplifier`s putput is low also. During the switched-off part of the amplifier`s cycle, the impedance looks like an open circuit. Over an entire cycle, the tube`s output impedance has an average value.

A pi-network is an impedance transformation device which does not completely isolate its input from its output, so a tube on its input has its shunt impedance transformed to some value across its output. Its resonance can linearize the signal.

Best regards, Richard Harrison, KB6WZI

Hi Richard,

On reviewing the paper you sent me I=92ve given a lot of thought
concerning the source of the induced current flowing in the external
resistance, R, the load of the plate of the tube. You say the source
of the I^2R power dissipated in R is plate resistance, Rp. However, as
I read Par 7.2 on Pages 140 and 141, the reality of Rp is described in
there, but only indirectly, thus requiring a deep inquiring mind to
ferret it out. For me, it takes a leap and a stretch to understand
that Rp is the source of the I^2R power delivered to R.

In Par 7.2 the author says this power is supplied by the kinetic
energy of the electrons in the beam. It takes no great amount of
mental concentration to understand that that statement is true. But
where I see a tangential approach to describing Rp is in the statement
that =93Since each electron in the beam faces a decelerating electric
field due to I^2R, it loses an amount of energy eIR during its flight
from the grid to electrode P.=94 This energy is lost, of course, because
the plate voltage is decreasing due to the increase in voltage drop IR
across R, caused by resistance Rp. We know, of course, that although
Rp is real, it is non-dissipative because it is not a physical
resistor, but is only the result of the ratio deltaE/deltaI.

Again quoting from Par 7.2, =93It is evident that IR must be smaller
than the voltage to which the electrons have been accelerated in order
that they reach P.=94 I understand this to be caused by Rp. However,
this still doesn=92t make clear that Rp is the source of the I^2R power.
Only until we see the quote =93=85the total power lost by the electrons in

the interelectrode region is (equation 7.12), which is equal to the heat power dissipated in the resistance (R) by the induced current.=94 does the reduced power seem to have any relevance to Rp.

Now continuing the quote from Par 7.2, =93The remaining part of the electron=92s kinetic energy is transformed into heat energy when they strike electrode P.=94 It=92s my understanding that this is the energy that=92s dissipated in the plate, causing it to heat.

However, the relationship between energy lost in the interelectrode region and the energy dissipated in R seems to say that Rp is the source of the energy dissipated in R, but it is difficult for me to accept that relationship. I find it difficult to accept that a loss in energy due to decelerating field in the interelectrode region could be the source of the energy dissipated in R.

Richard, can you help me out here in understanding this concept, if it=92s really true? It seems to me that the loss of energy due to Rp is simply energy that was never developed in the first place due to the deceleration of the electric field in the interelectrode region.

Walt

Memory has usual cob webs. Help clear it.......

When I feed twinlead, seems I might use a small fluorescent bulb to show how it's doing.   If a small fluorescent bulb will do this, do I just tune for "max smoke" while holding it near the twinlead?   Can't recall if a small flourescent bulb will do this or not.

If radiation is cancelled, not sure how it would fire.

I vaguely remember we used to use twin lamps, wired backwards for this purpose.   One way you had SWR on one side;   the other way you had SWR on the other side.   Neither light being lit meant good SWR.

Hi OM,

What you call fluorescent, I assume, must mean a small NE2 neon
indicator bulb which would be suitable to what you describe.

> If a small fluorescent bulb will do this, do I just tune for
>"max smoke" while holding it near the twinlead?   Can't recall if a small
>flourescent bulb will do this or not.

It is going to be an indication of "something."

>
>If radiation is cancelled, not sure how it would fire.

Within close proximity (about 3 to 5 times the wire separation), you
still have a sense of each wire. Further away, there is so little
difference in distance to either of them, that they both add with
cancellation.

>I vaguely remember we used to use twin lamps, wired backwards for this
>purpose.   One way you had SWR on one side;   the other way you had SWR on
>the other side.   Neither light being lit meant good SWR.

This must be the cobwebs you speak of. Other than LEDs (and I think
you would have specifically said so if your indicators were these),
lamps have no sense of current direction. Example, what would happen
if you reversed the plug to your table lamp? Would it suck light?
Have you ever put in a fluorescent bulb with the wrong polarity?

the solar wind is well know and easily studies with the satellite data
available today. but it is not an aether, the interplanetary plasma
does not propagate the light from the sun, it just gets in the way.

i hate mechanical analogies, they lead to too many misconceptions.
the last photon question was meant to be rhetorical.

I have vague recollections of a reflectometer using diodes, lamps and
300ohm twin feeder.  Maybe in an old copy of Radcom...

RB-

My cobwebs are probably worse than yours. As a teenager back in the
50s, I used a "Full Windom" antenna (off-center-fed-dipole) fed with 300
Ohm TV twin lead.

The SWR measurement circuit I used probably came from an ARRL
publication. It consisted of two 6 Volt dial lamps connected to each
end of a section of twin lead. I think it was two or three feet long.
The whole thing was taped to the transmission line. There was a
connection at the center of this on one side to one side of the
transmission line.

As I understood it, one lamp was supposed to glow and not the other. I
think both of mine glowed, but one was definitely brighter. Of coarse I
did not know what I was doing and had no real understanding of SWR. I
made contacts, so never worried about it!

Using a fluorescent tube, I would expect it might glow at points along
the transmission line where voltage was high and extinguish where
voltage was low. With a low SWR, there would be no high voltage points.
Or maybe no nulls?

I can only relate an experience I had in my house in Minnesota. We had a
long hallway and I could just shuffle my feet and the fluorescent light
I was carrying lit up from the accumulation of charge. Free, well almost
free light. A guy in the S.F. bay area has a house near a radio
transmitter and his garage is pretty well lit by 4 foot tubes he has put
around.
YMMV.

Try this.. I had an Ampex tube amplifier driving a high voltage
transformer and as the music danced (in my head) the patterns were
dancing to the same beat. I just drove the input of the Ampex with the
output audio line. Yes, that was in the 70's and yes we were all stoned.
I don't think that anyone else tried that combination, but it was way cool.

Whatever it was it was sure pretty and tube had ripples from both ends
that we could just watch. You would almost have to see it to believe it.
Kind of like visible standing waves going the length of the tube.
I think that kind of thing would kill any new solid state amps.

Bill

Hi Bill,

I just now ran into one of your earlier posts regarding insomnia. I
have some important info for you, which I'll email to you if you'll
give me your email address in a email to me, which is walt@w2du.com.

Walt

Darn, Bill, I don't know why this forum deletes part of an email
delivered in the text of a msg. The word preceding the @ is walt.

Hi all

First the first: Sorry Szczepan, do not feel upset I wanted to say
"Me" don't go off topic with my own answers, not you.

Very interesting comments!
I think we must agree on meaning of words and basement concepts
employed to discuss these matters, otherwise we end up talking about
different "things" (Babel curse what confuses our tongues). If we do
not agree with meaning of, for example, "interaction", how can we
reach an agreement on much more complex things that depend on this
word/concept?
This is not a criticism to anyone, is only my point of view about what
I think is a partial source of apparently irreductible positions in
the group.
I believe Richard, K1TTT and me, have sinchronized minds about
"Interaction" word/concept meaning. I suppose must be a more deep
underlying assumptios that make it possible. However I believe I
understand the "idea" underlying Cecil concept about "interaction" and
I believe I can "see" his point, To me, Cecil's interaction concept it
is a very common idea, I do not think Cecil be a "hard to die" man :>)
I think we have to do our more honest efforts to sinchronize ideas.

I do not want to go off topic, but let me bring a couple of thinkings to the table (they are not mine).

* Students come into our classrooms with an established world-view, formed by years of prior experience and learning.
* Even as it evolves, a student's world-view filters all experiences and affects their interpretation of observations.
* Students are emotionally attached to their world-views and will not give up their world-views easily.
* Challenging, revising, and restructuring one's world-view requires much effort.
(from http://srri.umass.edu/topics/constructivism)

Why these above things would not happen to me?
.....
Returning: Cecil, given A+B=3DC, do you you see C as result of an interaction (or mutual action) among A and B, or C a simply result of A added to B?
Another question to clarify my undestanding of your propositions: do you see waves interacting themselves in a discontinuity, or you see them interacting with the discontinuity? or both phenomena at the same time?. Change discontinuity for load and please tell me.

Richard, you said: -"Because" leads to superstition-; you are pointing to causal relations?
I believe was you who said dislike representations, if it is yes, were you aiming to create mental images of physical phenomena?
Here we often use the word "methafor" in figured sense instead "analogy", for example, "my car it is as strong as a locomotive" it is a true methaphor. In metaphor, there are two levels or terms: the real (my car) and evoked or imaginary (locomotive). Coulored water is it a true methaphor or an analogy?

Simple analogies as useful things until one (or more) of they not work... then, ciao analogy..!, not so bad :>), however... notice!, our ideas are not equal to the "out there" world. Concepts, models, (mathematical models also, of course)... are not they our mind's "analogies" "out there" sensorial/injstrumental perceived world?
These are not trivial epistemology issues, our "observer" leads directly to the question about "Is the moon there when nobody looks?" (N. D.Mermin). When we go out of our classic-simplistic-realistic-traditional ham world... "we are in troubles, Houston", slippery soil!, I make the sign of the cross! :>)

K1TTT said: -Standing waves are a figment of your instrumentation-. My dictionary translates "figment" as "product" or "chimera", please, tell me what word should I use to correctly read the sentence?

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Radio waves and sound are in full analogy.

>K1TTT said: -Standing waves are a figment of your instrumentation-. My

Waves always travel (pressure or voltage pulses). If the wave interact with
the reflected one than the places where the pressures/voltages change are
standing.

The reflected wave cam be weaker if the mirror is partialy transparent (or
if an absorbtion take place).
S*

The aether in sense of medium for light propagation.

> the interplanetary plasma
does not propagate the light from the sun,

In the interstellar medium (ISM) are ions, electrons and dust.
http://www.astronomynotes.com/ismnotes/s2.htm

The medium are the electrons ony. The rest are contaminations, like the fog
and dust in the air for the sound waves.
Do you see any sensible another solution?

I apologize for not recognizing that. Words don't always convey the
intended context.

in this context figment=3Dproduct. often used to describe something that is a result of an over active imagination. the only reason you can see standing waves is because a measurement or observation makes them look like they are 'standing' when it is really the interaction of two or more regular traveling waves.

the electrons can not do it either.  there are not enough of them and
they move too slowly in the plasma to propagate light.  these are
easily measured, you can watch the density directly using the ace
satellite web page and calculate the speed of longitudinal waves if
you want, but it won't be anywhere near light speed.

> A added to B?

Of course, there are all types of "addition", e.g. arithmetic, algebraic, voltage phasor, Poynting vector, scalar power, superposition, merging, mixing, ... Which type of "addition" is appropriate depends upon the nature of what is being added.

Simply put, if A + B =3D C creates an irreversible result, then A has (obviously?) interacted with B. If the result is reversible, then A has not interacted with B. For the great majority of cases, superposition does not result in interaction. For the great majority of cases, interference does not result in interaction. For some (special?) cases, superposition (plus associated interference and wave cancellation) results in interaction and the result is irreversible. Non reflective glass is an example of wave interaction. The internal reflection cancels the external reflection and the energy in those two reflections changes directions. A Z0-match at an impedance discontinuity in an RF transmission line is another example. Again, if two waves are coherent, collimated, and traveling in the same direction, those two waves will interact, i.e. their superposition result is not reversible.

what exactly is the 'interaction' and why is it unique to that special coherent, collimated, etc, case? if two waves can 'interact' in that case there should be other evidence that they can interact in other situations. just because a+b=3Dc doesn't mean that a and b have magically disappeared for some reason, in mathematics c=3Da+b is just as valid and implies that c is made up of a and b... or using your water analogy, adding one pint to another pint doesn't magically cause them to 'interact' in some way, the original water is still there, perhaps indistinguishable from each other, but still there. it may be convenient to represent the result of summing an infinite series of reflections as a single number, but it is not necessary.

This is not a forum -- this is a newsgroup on usenet. If you wouldn't use the google group kludge to attempt access into usenet, you would not see such additional kludginess in your postings. And, your postings are more apt to be seen by folks that don't killfile googlegrooper postings outright due to all the spam that flows in from that seweer.

Is it not obvious that when two reflected waves cancel in one direction, as at the surface of a 1/4WL thin-film coating on glass, and their combined EM energy is redistributed in the opposite direction, that those two waves have interacted, i.e. have suffered a permanent change and have lost their original identities?

Is it not obvious that when two waves are traveling two different paths where the incident angle is, e.g. two degrees, that those two waves will superpose and interfere throughout a certain space after which they emerge intact, unaffected, and have obviously not interacted, i.e. they suffered no permanent change and have maintained their original identities?

Did superposition occur in both cases? Yes. Did interference occur in both cases? Yes. Did wave cancellation occur in both cases? No, just in the non-reflective glass case.

Consider a transmission line with an SWR of 5.83:1. The sourced power is 100 watts. The forward power is 200 watts. The reflected power is 100 watts. All of the reflected power is redistributed back toward the load at a Z0-match through reflection and wave cancellation. Zero reflected power is incident upon the source.

Does the 100w source wave lose its identity when it merges with the 100w of redistributed reflected wave to become the 200w forward wave? Is the steady-state load energy coming from the source wave or the redistributed reflected wave or both? Seems to me, it is obvious that the two original component waves have interacted and lost their original identities for good if they are pure coherent sine waves traveling in the same direction confined to a coaxial transmission line.

I want to make a simple transmitter to use as a locator beacon. But the source would be in the ground (anywhere between 3 - 10ft). The receiver would need to locate it, much like a metal detector would except it would be a small hand-held "wand" with a LCD giving the direction and signal strength.

I'm not sure of the signaling to use therefore I'm not sure of the antenna required. But, it would need it to follow part 15 of the FCC rules/regulations (none hazardous and allows required interference).

I am completely new at this sort of technology. I have created circuits before using L555 timer, 4046Phase Loop, etc. But I've never went farther than building simple demonstration circuits. I wondered if there was anyone on this list that may be able to shed some light on what I would need and/or how I would use them (a schematical description), or even point me to the "yellow brick road".

Thanks!

Try burying a WiFi dongle and see what you get. 2.4gHz has the advantages of being COTS (commercial off the shelf technology), easy to build directional antennas, cheap and easily adapated to digital technology.

It also has the advantage of being legal in almost (if not) every country in the world.

I'm not sure it will reach through 3-10 feet of dirt, but I expect that anything much above 15khz will have that problem.

Geoff.

Hi Walt,

The point I have been emphasizing is that the plate resistance is real, where real is the conventional meaning of heat following current. The authors expresses this in all the conventional usages and mathematical expressions of heat, velocity, kinetics, mass, collision, current, voltage - everything you would find in an ordinary resistor.

As for indirectness, no single section encapsulates the entire topic.

However, the remainder of the chapter does. Don't stop early to examine the sidewalk to ignore the destination.

As so often happens in our newsgroup, the discussion of many topics stalls at the freshman level and is regarded as complete in every detail and nuance. "Physical Electronics," is far in advance of those thoughts.

Hi All,

This and Myron's reference appear to fill in all the blanks and should brush away the cobwebs.

What is described above appears to be that of a directional coupler. I would suspect that the connection between it and the line is through a capacitor, and the line proximity serves the inductive coupling. I also presume the "transmission line" was also twin line, otherwise none of this would work. The action of the directional coupler is what separates the forward and reflected energies.

I don't know what you are hiding, but some of the ELT (Emergency locator transmitters) are tracked by satellite, and if you set one off sirens go off in control centers.

Great if you are trying to get rescued, a disaster if you want to find your "stash".

Geoff.

Hi Miguel,

Language would have us believe that causal relations "be" from "cause." Common language sometimes uses "because" as a bridge between phrases without necessarily implying causality - in other words, the word "because" is verbal noise when that happens. "Because" is often a one word reply to a child's question "Why?"

>I believe was you who said dislike representations, if it is yes, were
>you aiming to create mental images of physical phenomena?

Oh, I do that all the time. However, I do not mistake representations
as being the real thing. In other contexts, they are more real than
the real thing. So, if there is dislike, it comes from seeing
inferior representation when better work requires so little more
effort.

Both. But context should resolve that, or it could still be both.
That is why metaphor and analogy are so dangerous. That is also why
it is so useful in fiction. We get enough fiction here.

Hi Miguel,

How well does this translate to Spanish?

As I've offered, native speakers are often the poorest communicators
in their own language. Imagine trying to visualize an optical
metaphor when this comet hits the windshield.

The Consultant SEO is known for providing the best SEO services to its
customers. With the best and highly competent SEO experts on its team
it is not surprising that The Consultant SEO makes available to its
customers and online businesses the best SEO services, of the many
link building services  provided by The Consultant SEO, blog
commenting service is one. Blog commenting service  is of great value
to people who own websites, for it helps them raise their search
engine ranking and amplify traffic. Blog commenting service provided
by The Consultant SEO ensures more and more back links to your sites
and also helps you build up your SERPS.

Probably, but the real answer is that the performance will be different.
You'll need to try it out. The T-feed might actually be quite good on
the lower frequencies - especially 80m - for long-distance contacts. But
you will need a good ground or counterpoise system. Ideally, your
counterpoise should be around a quarterwave (for all the bands where you
use the antenna as a T), so, if it looks promising, you might like to
```

try multiple wires.

The main problem with any endfed antenna, when fed directly in the
shack, is that you will have a lot of RF in the shack - and you will
also pick up more 'domestic' QRM and hash, usually from things like
switchmode power supplies and all the other 'non-amateur-friendly'
equipment deemed essential for modern-day living.

no, art is stuck in newton's time, so you aren't that far apart.

fortunately maxwell's equations work just fine for macroscopic stuff like hams use, so you are still ok with those. when someone writes an antenna program that uses qed you might want to upgrade though. and newton still works for most cases you will ever run into, though it would fail to explain some effects if you carried an atomic clock on a high speed jet or tried to orbit your own satellite. Ohm's law is still fine for anything you will do also, unless you really tried to get into superconductive antennas, then you might have some problems.

> Tonight I said to me: -the worst term that you could use, Miguel, was "ether"- :>), because "ether" is a hipotetical MATERIAL thing, ...

The first guesses at the nature of the ether were obviously wrong. But we now know that if you replace the word "ether" with "quantum soup" in your statements about ether, that you will be technically correct as far as quantum physics can determine. Take a look at the Casimir Effect to see if empty space is really empty. In reality, totally empty space would be outside of the space/time of the known universe.

http://www.answers.com/topic/casimir-effect

> I needed know what represent that in a line discontinuity (in a load seems obvious) to better understand Cecil's examples in web page (http://www.w5dxp.com/energy.htm).

At the junction of two transmission lines, if the characteristic impedances (Z01 and Z02) are not the same value, then reflections and subsequent interference will usually occur. This is similar to saying: At the junction of two light mediums, if the index of refraction is not the same value in both mediums, then reflections will occur from a (laser) light beam normal to the two surfaces. I am specifying normal=3D90 deg. and ignoring refraction which is of little importance in an RF transmission line.

> Before continue I want to do a comment to know if we agree (more or less). We partially think with words or symbols, words and symbols represent concepts or perceptions, concepts are not "out there", as Einstein said they are: "free creations of human mind".

And Shakespeare said:

"What's in a name? that which we call a rose
      By any other name would smell as sweet; ..."

There's not much argument between the definition of "rose" and "rosal". I call that a 1st level abstraction. Things get a little more complicated at the Nth level abstraction. If in Texan I said, "Ah reckon Ah'm gonna amble over yonder directly", you might have trouble with the meaning (except for "amble". :-)

> Cecil I want to ask you if you are using "photon" term to methaforically refer to "light".

No, EM (light and RF) waves are known to be quantized and therefore consist of photons. The reason that I refer to the photons is that photons must obey a certain set of laws of physics. For instance, they must move at the speed of light in a medium. Photons cannot stand still in a standing wave. Therefore, any theory of physics that requires photons to stand still is incorrect. That would include the particular interpretation of the lumped-impedance model that some folks are pushing here on this newsgroup. The only time I will refer to photons is when the presented EM wave theory contradicts the accepted laws of quantum physics. It is simply an attempt at trying to keep some folks honest.

The point is that what we see at visible light frequencies also happens at RF frequencies but we cannot see RF. By switching to a visible light example, I can point out the errors of someone attempting to pull the wool over the eyes of the unwashed masses.

> (I do not forget Roy's article, I'm still trying to sort out all the
> puzzle pieces).

Note that Roy seems to be completely ignorant of this fact of physics: "... the photons are redistributed to regions that permit constructive interference ..." as described on the Florida State web page at the bottom of the page:

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/
waveinteractions/index.html

In an RF transmission line, the only "regions that permit constructive interference" is the single opposite direction in the transmission line from the direction of destructive interference. In the absence of a localized source of energy, any destructive interference in one direction (at an isolated impedance discontinuity in a transmission line) must be balanced by an equal magnitude of constructive interference in the opposite direction. The conservation of energy theorem will have it no other way.

If you are familiar with the scattering parameter/matrix equations, much can be learned by analyzing them. Note that the equations are phasor math, not simple algebra equations.

http://www.sss-mag.com/pdf/hpan95-1.pdf

b1 =3D s11*a1 + s12*a2

b1, the total reflected voltage toward the load, is equal to the forward voltage (from the source) reflected from the impedance discontinuity, phasor added to the transmitted reflected voltage through the impedance discontinuity (from the load).

b2 =3D s21*a1 + s22*a2

The total forward voltage toward the load, is equal to the transmitted forward voltage through the impedance discontinuity (from the source), phasor added to the reflected voltage (from the load) that is re-reflected back toward the load by the impedance discontinuity.

The a and b parameters are voltages normalized to the square root of Z0. Squaring both sides of each equation will yield the interference terms in watts, that indicate where the energy goes, i.e. which of two directions in a transmission line.

Note that if b1 =3D 0, there is (by definition) total destructive interference between s11*a1 and s12*a2, i.e. the same as a Z0-match in a transmission line.

Even if no classic reflections (associated with a physical reflection coefficient) exist, as in Roy's foot-for-thought example, destructive interference at the source resistor will cause some or all of the energy in the reflected wave to be *redistributed* (redirected) back toward the load as constructive interference. Since the wave cancellation causes a reversal in direction of reflected energy (somewhat resembling a reflection) Walter Maxwell, in "Reflections" defines that reversal as a "reflection from a virtual short". Presumably the virtual short (or open) concept would also apply to a 1/4WL thin-film coating on non-reflective glass.

Miguel, "redistribute" is not in my Spanish/English dictionary but "redirect" is and might be a reasonable mental substitute for you to conceptualize. From the FSU web page, ...the photons are redistributed (i.e. redirected) to regions that permit constructive interference ... .

Hi Richard,

I sincerely appreciate your kind words concerning my humanity, and I'm proud to have you call me Sensei. I have always somehow doubted your feelings for me as a person, but your words above have relieved that feeling, Thank you.

As for our disagreement on image matching, I remember reading many years ago in books concerning networks involving telephone circuits that dealt only with resistive terminations. Those readings did specify that with image resistances the resistances were the same in both directions. Nothing was said in those books concerning reactance in the circuitry. Apparently we have different editions of Terman. Mine doesn't discuss R as the remnant of conjugation, so if only R is considered in the image impedance I can concur with you on this issue.

I also want to be clear on my position concerning plate resistance Rp as the source resistance of the RF power amplifier. My position is that it is not. I do understand that Rp is a factor in determining the value of RL that appears at the input of the tank circuit, but not the source of power delivered at the output of the tank circuit. Rp is a non-dissipative resistance, not a resisTOR with physical characteristics. I consider the voltage-current ratio R appearing at the output of the tank circuit to be the source resistance of the RF power amplifier. If you do not agree with this position then I guess we'll just have to agree to disagree, unless you can find some way to change my mind.

I thank you again, Richard, for your kind words.

Walt

"lu6etj" <lu6etj@gmail.com> wrote news:0d91fd84-c798-4391-8e90-I do not have useful knowledge in laser either.

>

>I am interested in your optical analogy because analogies often are useful to visualize a new thing knowing old things, it does not matter if we use RF concepts to aproximate optical things or vice versa, analogies are useful crutches (muletas in spanish). Even I agree at our concept that electromagnetic spectrum includes RF waves and ligh waves and they are the same phenomenon, I think that is a result of great insight and efforts of the human mind, it is not so evident. We see light, we sense infrared radiaton, but we can not perceive well RF without instruments (unless we introduce ourselves in a micowave oven

or burn with the antenna, of course).
To concentrate light we only need a piece of glass, to do the same on HF RF region we need large wire antenna arrays. Because of this we often need (or employ) very differents models to deal with the "same thing". Probably Maxwell equations solve all of them, but they are difficult ladies to deal :>).

Maxwell equations are wrote by Heaviside.

>Reconciling optcs models with electric models have its difficulties, but can be productive undoubtedly I believe.

Now light is produced with the electric device:
"As the electrons are undergoing acceleration they radiate electromagnetic energy in their flight direction, and as they interact with the light already emitted, photons along its line are emitted in phase, resulting in a "laser-like" monocromatic and coherent beam. The mirrors show in the sketch below are superfluous, as all the light is emitted in one direction anyway."
From: http://en.wikipedia.org/wiki/Halbach_array

When electrons oscillate they disturb the "electron see" and that are waves.
To achive the oscillations we use different devices.
The Halbach array is for light. The dipole for RF. For radar and microwaves the another.

Hi Walt,

Go to the index and look up Th�venin. The material should be found in two areas:
1. Circuits with Lumped Constants - Th�venin's Theorem - Impedance Matching
2. Audio Voltage Amplifiers - Resistance-coupled Amplifiers

>Rp is a
>non-dissipative resistance, not a resisTOR with physical
>characteristics. I consider the voltage-current ratio R appearing at

I will use your own data.

I will be concerned with nothing else outside of this specification as this is a discussion of the "real" Tube, and a power supply which will be considered as loss-less.

First. There is one current loop throughout the entire system.

Second. Unique to a tube path within that current loop, there are two characteristic current types. These are the convection current WITHIN the cathode-plate interval, and the induction current that completes the loop from plate to cathode through conventional power supply wiring.

Third. The induction current's mobile electrons move at a rate of meters per minute; whereas the charge mobility is near light speed.

Fourth. The convection current's mobile electrons (a literal particle stream in a vacuum) move at a rate of near light speed. The term "near light speed," in this case, is limited by the plate potential of 800V and can be computed; whereas the charge mobility is near light speed, but generally higher (and specifically higher for 800V) than the electron speed.

Fifth. It takes work to move an electron initially at rest to near light speed over the interval between the cathode and the plate with nanoseconds transit times.

Sixth. The electron gains kinetic energy from the field between the plate and cathode.

Seventh. The kinetic energy of the electron is converted into heat upon striking the plate, the heat energy being equal to the power supply energy expended in accelerating the electron.

I will forgo the math of how considerable the resistance, power, and heat is. All can be found from the data quoted above. Clearly, the plate resistance is real in every sense of the word. It is the limiting factor of the current path hence it is the source resistance in every sense of the word.

The seven points I enumerate are from material drawn from a single source. I am sending you the full chapter treatment that speaks to this topic alone from:
"Physical Electronics," Curtis L. Hemenway, Richard W. Henry, Martin Caulton; John Wiley and Sons, 1962.

Others may ask for copies of this reference. Others may ask where the heat comes from, a topic I would enjoy elaborating upon. It is a very simple explanation that by using Walt's data above, can be rendered into Watts/Temperature with only the difficulty of pressing calculator keys. These values than can weighed against real and tested observation at the bench of the same tube in operation.

I cannot imagine anything else meriting discussion.

I all

Richard, I can not translate "Is yours dead?", I suppose means
something as "if it is my last word about it". Well...I do not believe
in witches but there are, there are! I shall not bet :>)

> Have you been following that story with Walt and myself?

Sorry, no. ocassionally I read the topic in this newsgroup long time

ago.
....
I agree Cecil, be indulgent with my poor translations, I should have written "I don not postulate Ether, without 'an' before", pointing - with the capital "L"- to our old friend "luminiferous ether"; quantic ether it is a different and very interesting stuff, isn't it?
I can not tranlate your Texan sentence, is a dialect? (patois?). Would you mind write it in basic "english for aliens" for me).
I do not quite understand this =3D> "Photons cannot stand still in a standing wave." -You do not ascribe to wave-particle duality notion?-

As I understand quantic numbers of HF energy are a such extremely small quantities that have unmeasurable effects, I understood (or suppose) you wanted mean quantic physics born of fail of classical electrodynamics to explain all phenomena.
When I pointed to dimensions of transmission line space vs tridimensional space I am thinking of what you called (named?) "redistribution" as meaning the only possible solution in such space is redirection (or reflection). Is it OK?
From me understanding "reflection" is a way of "redirection" of light that obey to the reflection law of optics, in transmission line space I think would be synonymous (at last in spanish language). Do not you agree?
Anyway, I think that classic physics is enough to explain phenomena on extremly low quantic number systems, as HF energy or cars in movement :>)

Returning to analogy. I can not realize how associate Zc changes to refraction because I learnt refraction as a differente speed of light medium phenomenom. Give me a hand.

["re" it is only a prefix, look for "distribute" (or verb "distribuir" in spanish =3D> "Give something its timely placement or convenient location". I bet it has same meaning in english]

Before advance more. I am not yet quite discern your (plural) conceptual differences. Please remember that I did a question and you answer with concepts of advanced stages of your discussion. Until now - seems to me- Owen sustain our clasic Terman et al teachings and is critic of Walter's theory; you too but from different point of view (redistribution of energy, interference, photon laws, etc). I do not know yet Roy's differences, and Richard would support all Walter's hipothesis.

Also seems to me that a piece of discussion revolves around "truthness" (in weak sense of word) of respective models more than capacity of each one to give correct results to empiric measurements. Perhaps a little summary of coincidences and differences can serve to other readers, and me, obviously :>)

73 and good weekend to all

Miguel Ghezzi LU6ETJ

It was a Quantum joke. It has groans AND laughs until you read it.

>> Have you been following that story with Walt and myself?
>Sorry, no. ocassionally I read the topic in this newsgroup long time
>ago.

Too bad. I find plate resistance an interesting application of macro
and micro action. I thought you would too.

>"Photons cannot stand still in a
>standing wave."

Gad, what an awful statement.

>As I understand quantic numbers of HF energy are a such extremely
>small quantities that have unmeasurable effects,

They are measured. Your "understanding" is an example of how a metaphor can throw you into the ditch. Trying to go down the optical path to discuss RF will find you walking in the bushes.

>Zc changes to
>refraction

Gad, another awful statement.

>["re" it is only a prefix, look for "distribute" (or verb "distribuir"
>in spanish => "Give something its timely placement or convenient
>location". I bet it has same meaning in english]

Your English is fine.

>Richard would support all Walter's
>hipothesis.

No, I don't support Walt's hypothesis, I support his data. Walt and I disagree about Plate resistance being "real." It is a very small step over a very large boulder. (Quantum tunneling would make it easier.)

The "problem" with Plate resistance seems to have arrived through creationism - a novel superstition instead of a simple superposition.

>Also seems to me that a piece of discussion revolves around
>"truthness" (in weak sense of word) of respective models more than
>capacity of each one to give correct results to empiric measurements.
>Perhaps a little summary of coincidences and differences can serve to

The word you are trying to find is "validity," that is, if this is a scientific issue. You are right about "truthfulness" if it is a religious issue. Or possibly a boolean logical result if we left the realm of analog.

Validity is a result of testing results (scientific method) against expectations.

Truth is a result of burning someone (auto de f�) until they agree with you.

Choose your company with care. Do they work at the bench, or do they play with matches? :-)

Hi Richard,

Thank you for sending the copy of the paper you referenced. I've been
reviewing it this afternoon. Although I understand that induced
current results from a moving charge, I'm not as comfortable
discussing  the Rp issue in terms of charges as I am with currents, so
I'm having a little difficulty in coming to grips with Rp while
reviewing the paper. Consequently, I need a little more time
assimilating the info before replying further in hope of resolving our
difference on the subject.

I'll be back with you as soon as I'm ready.

Looks like my follow up post didn't make it through.

Richard I intend these three ground rods to be the start of grounding my station, not as a counterpoise for one of my antennas. These will be bonded to my radios and the electrical service entrance ground.

Why do you say this does not make an RF ground?

Thanks, Bob

Hi Bob,

If by "this" you mean the three rods, then they will NOT make an RF ground.

Of necessity due to wavelength, your ground must be spread out (not buried) to one quarter wavelength. For 160M, your radials (not ground rods), should extend 40 meters from your radiator.

Classically, you would need 120 radials for an RF ground.

Classicism and practical reality diverge, so there are variations on
all of this EXCEPT ground rods do not make an RF ground.

Miguel, your English is a magnitude better than my Spanish so don't worry about it. "Quantum ether" are two words that I have never seen together before. Maybe you will be famous for that concept.

> I can not tranlate your Texan sentence, is a dialect? (patois?). Would
> you mind write it in basic "english for aliens" for me).

Northern Americans cannot understand it either. :-) The translation is: "I think I will walk over there after awhile." The Texan word "amble" came from the Spanish word "amblar".

> I do not quite understand this =3D> "Photons cannot stand still in a standing wave." -You do not ascribe to wave-particle duality notion?-

Some of the RF gurus will try to convince you that the energy in RF standing waves is standing still. But since those RF waves consist of photons which must necessarily move at the speed of light in the medium, they are dead wrong. The correct concept is that a pure standing wave doesn't transfer any *net* energy but the two equal component traveling waves, forward and reverse, are still moving at the speed of light in opposite.

> As I understand quantic numbers of HF energy are a such extremely small quantities that have unmeasurable effects, I understood (or suppose) you wanted mean quantic physics born of fail of classical electrodynamics to explain all phenomena.

The point is that the photonic energy in an RF wave cannot stand still. That defeats the argument that reflected waves don't exist or don't contain any energy. Such is simply nonsense.

> When I pointed to dimensions of transmission line space vs tridimensional space I am thinking of what you called (named?) "redistribution" as meaning the only possible solution in such space is redirection (or reflection). Is it OK?

Light waves can be reflected, refracted, and/or redistributed in any 3D direction. RF waves in a transmission line can only flow in two directions, forward and reverse. That simplifies things considerably. Coherent waves flowing in the same direction in a transmission line suffer permanent interaction.

> From me understanding "reflection" is a way of "redirection" of light that obey to the reflection law of optics, in transmission line space I think would be synonymous (at last in spanish language). Do not you agree?

Yes, but wave cancellation accompanied by destructive interference can also redirect EM energy. Wave cancellation is what w7el is missing in his food-for-thought article.

> Anyway, I think that classic physics is enough to explain phenomena on extremly low quantic number systems, as HF energy or cars in movement :>)

Yes, but when classic physics allegedly doesn't obey the laws of quantum electrodynamics, something is wrong, and quantum electrodynamics wins every time.

> Returning to analogy. I can not realize how associate Zc changes to
> refraction because I learnt refraction as a differente speed of light
> medium phenomenom. Give me a hand.

For the purposes of RF waves in a transmission line, you can forget refraction as an irrelevant effect.

> ["re" it is only a prefix, look for "distribute" (or verb "distribuir"
> in spanish =3D> "Give something its timely placement or convenient
> location". =A0I bet it has same meaning in english]

Yes, that is probably correct.

> ... you too but from different point of view
> (redistribution of energy, interference, photon laws, etc).

My concepts are directly from the field of optical physics. You might want to obtain a copy of "Optics", by Hecht. It is available in Spanish:

http://www.astronomyinspanish.org/slm/eng/book/coll/optica_hecht

This book will teach you more about EM *energy flow* than any RF engineering book that I know of.

> Perhaps a little summary of coincidences and differences can serve to
> other readers, and me, obviously :>)

The model that w7el uses for his food-for-thought article on forward and reflected power is obviously wrong because it doesn't indicate where the reflected energy goes. When a model confuses the user and obviously doesn't represent reality, it's time to upgrade to a better model. The EM wave model used in optics does necessarily track the reflected energy because optical physicists cannot easily measure voltage.

Hi All,

For others, there might be wonder at the meaning of induced or inducted current - or convection current for that matter. It would be useful to expand here in a new thread.

First. In the interval between cathode and plate, there are only electrons. In other words, there are no conductors as are found everywhere else.

Second. When an electron flows between the cathode and the plate, charge is moving. By convention, this is called current. It goes by a special label - convection current.

Third. The interval between the cathode and plate is part of a complete circuit that travels through the power supply, returns to ground and rises from ground to come to the cathode.

Fourth. For charge movement through the interval between cathode and plate, there is exactly the same charge movement through ALL wiring connecting the plate to the power supply, wiring from the power supply to ground, and wiring from the ground to the cathode.

Fifth. The charge movement throughout the wired circuit, by convention is called current. it goes by a special label - induced current.

The distinction between induced current and convection current is found in their transport media. One is metal, the other is vacuum. The convection (like convection heat) is electron movement in space which induces current in the wire. This induction is NOT like transformer induction. It has absolutely nothing to do with magnetic linkage. We could call it induction if the entire circuit were composed of wire. That is, the movement of one electron "induces" the movement of another electron.

Similarly (and tipping my hand about reflected waves), an extra electron push in the wiring will induce an electron in the tube to move. The current is inextricably locked in a dynamic flow. There is no new physics in this anywhere.

So why two terms? The necessity of this seemingly obscure point is to exhibit how heat is formed, and why the plate of the tube is a literal, real resistor in this circuit. Very few correspondents (read none but myself) to this board dwell on this, and they end up dismissing the real resistance of this specific and consequential source as a mathematical fiction suitable for only milliwatt signal generators.

Hi to all...

Richard, do you agree with Walter's theory on "Another look at
reflections" in reflections topic -out of plate resistance
differences-?

> The word you are trying to find is "validity,"

No, it was more near of your second =3D> "Truth", or "The Truth", the
metaphysical "truth" :>)

> Walt and I disagree about Plate resistance being "real"

What is "real" for you? For me it is a slippery word ever ready to
disputes, in knowledge matters makes us think of the "thing itself"
and with it, we quickly fall into endless scholastic discussions. With
models "the thing" it is a little more ease, models only must be
internal and measurements consistent. Models are neither "True" nor
"Real", they are modestly "valid" :>) What do you think?
....
I believe I am in a privileged position because my english weakness :
when I am about to disagree with you, I tell me -"probably you do not
translate well, Miguel, ask again"- and when you answer to me then
voil=E1! I do not disagree... Viceversa, perhaps language give me a
second chance with you because you are more forgiving with me :>)

Example:
Miguel =3D>
> I do not quite understand this =3D> "Photons cannot stand still in a
> standing wave." -You do not ascribe to wave-particle duality notion?-
Cecil =3D>
> Some of the RF gurus will try to convince you that the energy in RF
> standing waves is standing still. But since those RF waves consist of
> photons which must necessarily move at the speed of light in the
> medium,

So, now I believe what he is trying to tell me is stationary wave is a measured time dependent magnitude resulting of two near speed of light traveling waves, manifestating in our measurement apparatus (observer or "load" as said Richard)... It is good to me.. Then, I do not care anymore the ugly (nasty?) word "photon" :>), and finally to my joy, next Cecil sentence confirms my translation/interpretation!.

> Coherent waves flowing in the same direction in a transmission line
> suffer permanent interaction.

It is difficult to me reconcile superposition principle with "interaction", because in spanish "interacci=F3n" word means: "Action exerted MUTUALLY between two or more objects, agents, forces, functions, etc" (capitals are mine) And I learnt two or more electromagnetic waves can pass one through other by same point of the SPACE without recognizing themselves (unlike particles that "collide"), then, by definition, they not interactuate themselves at all.
We do not "see" any standing wave in space when two same path opposite direction RF rays cross themselves and there is not contradiction. Are you agree?
In transmission lines instead it is not easy to think that because more "tangible" standing wave voltages and currents make us think they are "interacting". What do you think about it?,

> but wave cancellation accompanied by destructive interference can
also redirect EM energy

To satisfy the energy conservation principle, isn' it? This produces a reflection, right?

> but when classic physics allegedly doesn't obey the laws of
quantum electrodynamics, something is wrong, and quantum
electrodynamics wins every time.

Could be classic electrodynamics be right but we are not applying correctly, and then classic model not become a losser in this matter?

I see you do not agree with some Roy Lewallen proposition: do you agree with Walter Maxwell on this topic?

Sorry (for me) Cecil "quantum ether" is not mine :>(

Thanks for optics book recommendation.

73

Hi Miguel,

Walt is not espousing a theory.

>> The word you are trying to find is "validity,"
>
>No, it was more near of your second => "Truth", or "The Truth", the
>metaphysical "truth" :>)

Then this will be great sport.
(sport: from Old French desport , pleasure ,
from desporter , to divert
- I assume it is not very different
from the Spanish desportes)

>> Walt and I disagree about Plate resistance being "real"
>

They have what is called "internal consistency."
>.......
>I believe I am in a privileged position because my english weakness :

I have designed natural language parsers (NLP). Non-native speakers
of English know the language far better than native born speakers.

That is your privilege.

>when I am about to disagree with you, I tell me -"probably you do not
>translate well, Miguel, ask again"- and when you answer to me then
>voil�! I do not disagree... Viceversa, perhaps language give me a

I have lived in more countries and spoken more languages than most
here. There are many here that speak and write perfectly poor English
that makes better sense that some of the strange statements you are
trying to parse.

>Example:
>Miguel =>
>> I do not quite understand this => "Photons cannot stand still in a
>> standing wave." -You do not ascribe to wave-particle duality notion?-
>Cecil =>
>> Some of the RF gurus will try to convince you that the energy in RF

You have the second privilege of understanding a confused statement when you see it. This is language independent.

>We do not "see" any standing wave in space when two same path opposite
>direction RF rays cross themselves and there is not contradiction. Are
>you agree?

To see is to witness, or be an observer (from the Latin observare, ob- over, -servare watch). When two light waves illuminate the same load, and the load is observable, you see the combination of two energies at that load.

A standing wave does not exist until you measure the combination of the contributions at a point. You can, of course, populate a large area with many point-loads if you wish to map a region. Under very controlled circumstances, you will get to see a nice pattern.

The sport is found here: Of course, you could see the same pattern at the same points by the projection of an image upon them from one source.

Could you tell the difference between (1) that single source projected image and (2) the standing wave combination of several sources?

This is too much fun already, but.....

So, for Truth: Is a movie projector acted upon by the movie it projects? Was your camera happy because your photograph shows a smile? The Truth would say yes. What would Schrodinger see?

Does that help?

>In transmission lines instead it is not easy to think that because
>more "tangible" standing wave voltages and currents make us think they

>are "interacting". What do you think about it?,

A confused statement.

>> but wave cancellation accompanied by destructive interference can
>also redirect EM energy
>
>To satisfy the energy conservation principle, isn' it? This produces a

You are in the bushes.

>> but when classic physics allegedly doesn't obey the laws of

Let's see now. You have three things to figure out. RF, Light, and QED. I hestitate to wonder what could possibly follow if you prove to be to slow to figure these out. Perhaps sudoko patterns revealing the entanglement of strange attractors. (Sorry for the translation overload.)

And this started with Truth? :-)

Write when you receive more inspiration. (A supernatural divine influence on the prophets, apostles, or sacred writers, by which they were qualified to communicate moral or religious truth with authority; a supernatural influence which qualifies men to receive and communicate divine truth; also, the truth communicated.)

>The model that w7el uses for his food-for-thought article on forward and reflected power is obviously wrong because it doesn't indicate where the reflected energy goes. When a model confuses the user and obviously doesn't represent reality, it's time to upgrade to a better model. The EM wave model used in optics does necessarily track the reflected energy because optical physicists cannot easily measure voltage.

The intensity is also accurate.
The end of the dipole reflect and transmit. The proportion is measured as VWSR.
But for this you need the Electric Wave Model.
EM was stripped away by Royal Society in 1864.

Mr. S... please, you need to do 2 things... first, get a better
newsgroup editor or use the groups.google.com web site to post
replies, whatever you are using now messes up the indentation for
quoted text and makes it impossible to figure out what you wrote and
what is quoted. second, keep your 150 year old theories in threads
where they belong, they will only cause confusion to those who are
trying to discuss modern methods.

does it really matter what the mechanism of generating the heat is?
the fact that there is heat generated in the plate means there is
energy lost from the electrons, be it due to impinging on the plate
mechanically or due to the metal resistance it is still a loss of
energy. And since there is more heat when there is more plate current
we can model it as a real resistance. The only question is then, is
it linear or not. that should be a 'relatively' simple measurement,
and one that has likely been done by a researcher somewhere along the
line.

> all.

What you learned is usually true in free space. Two light waves can pass through each other at the same point in space without affecting or interacting with each other because they are *not collinear*. It is very difficult to align two light beams in free space such that they are collinear. However, it can be done in an interferometer.

http://www.teachspin.com/instruments/moderni/experiments.shtml

But in an RF transmission line, please understand that there is *no way to keep the RF waves from being collinear* since it is primarily a one-dimensional space with only two possible directions. Therefore, any two coherent RF waves traveling in the same direction in an RF transmission line, will interact and have a permanent effect. For pure sinusoidal waves, the transmitted wave, the re-reflected wave, and the constructive interference wave are all coherent and collinear and merge into a single forward wave flowing toward the load. The component waves become inseparable.

> We do not "see" any standing wave in space when two same path opposite
> direction RF rays cross themselves and there is not contradiction. Are
> you agree?

Eugene Hecht, in "Optics", describes standing waves of visible light in free space. I'm not sure that humans can "see" the standing wave detail because the frequency is so high, but standing waves of visible light can certainly exist in free space. If you can, please obtain a copy of "Optics". If one routed a standing-wave of light through a cloud chamber, it would become visible. I don't know if the human eye can resolve the high and low interference patterns but I'm sure instruments could detect it.

> In transmission lines instead it is not easy to think that because
> more "tangible" standing wave voltages and currents make us think they
> are "interacting". What do you think about it?,

Coherent collinear waves traveling the same direction in a transmission line superpose, merge, and interact. This invariably occurs at an impedance discontinuity point during interference immediately after normal reflections have taken place. RF waves traveling in opposite directions in a transmission line with a constant Z0, do not interact.

> To satisfy the energy conservation principle, isn' it? This produces a
> reflection, right?

Walter Maxwell defines it as a reflection. I am a little more careful and have adopted the following standards from optical physics. A "reflection" is something that happens to a single wave and corresponds to a physical reflection coefficient. A "redistribution" can be a reflection but can also involve interference between two or more waves. If superposition is involved, I use the word "redistribution" rather than "reflection". Walt lumps the concepts of normal reflection with wave cancellation and introduces the concept of a virtual reflection coefficient. Both approaches work. IMO, mine is slightly more detailed. In "Reflections", under the 1/4WL matching stub section, Walt proves that he fully understands the role of constructive/destructive interference in the redistribution of energy.

> Could be classic electrodynamics be right but we are not applying
> correctly, and then classic model not become a losser in this matter?

Yes, if w7el would recognize the energy content (V^2/Z0 watts) that exists in the voltages that he is superposing, he would be able to track the reflected energy from the load back to the source and then back to the load as a component of forward power.

> I see you do not agree with some Roy Lewallen proposition: do you
> agree with Walter Maxwell on this topic?

In his food-for-thought article, Roy neglected to include the effects of wave-cancellation/interference at the source resistor in his example. I don't think that Walter Maxwell has expressed an opinion on this particular subject of dissipation in the source resistor of a voltage source as specified by w7el. In a real-world amplifier, Walt asserts that the source resistance is non-dissipative while, for his food-for-thought examples, Roy specified a dissipative source resistance designed to eliminate reflections. Again, what he forgot to include is redistribution of energy due to wave cancellation, a concept well understood in the field of EM wave optical physics. He apparently does not understand the mechanism whereby the conservation of energy principle is honored so he is forced to falsely assume that reflected energy is not incident upon the source resistor. Nothing could be farther from the facts of physics as understood for decades in the field of optical physics. I was taught constructive/destructive interference energy concepts in my vector analysis classes at Texas A&M University during the 50's.

The only time photons are not generated is during DC steady-state with
no AC signal applied. If you can see the electron beam inside a vacuum
tube (and I have), the electron beam is necessarily emitting photons.
If the field surrounding an electrical current is detectable, the
electrons are emitting photons.

I have shifted the following post to this thread where it fits the context perfectly:

On Sun, 30 May 2010 06:59:58 -0700 (PDT), K1TTT <k1ttt@arrl.net> wrote:

>does it really matter what the mechanism of generating the heat is?
>the fact that there is heat generated in the plate means there is
>energy lost from the electrons, be it due to impinging on the plate
>mechanically or due to the metal resistance it is still a loss of
>energy. And since there is more heat when there is more plate current
>we can model it as a real resistance. The only question is then, is
>it linear or not. that should be a 'relatively' simple measurement,
>and one that has likely been done by a researcher somewhere along the
>line.

Yes.

This post is sufficiently informing for many. Others may take its lead and derive EXACTLY how much resistance, heat, power from the data provided by Walt and confirm the bench experience of real resistance within the source.

This response quoted above also corrects my mis-observation of my having the only perception of this universally experienced phenomenon. By count, we are up to two who acknowledge what is obvious.

A lot of folks, make the same mistake, in thinking that Electrical Ground and RF Ground are the same thing. They, clearly, are NOT, the same thing or even close to the same thing, unless you happen to be living on a Salt Marsh. Ground Rods, of any kind, are only Electrical Grounds. Rf Grounding is a Totally Different bag of cats. RF Grounds need to be engineered, by someone who is familiar with Antenna Design and Installation Procedures, for the particular Antenna and landscape, where the antenna is to be installed.

For you and Cecil I must make by hand the indentation for
quoted text . The rest are O.K.

>and makes it impossible to figure out what you wrote and
what is quoted.

> second, keep your 150 year old theories in threads
where they belong, they will only cause confusion to those who are
trying to discuss modern methods.

They should know that the physics and the math go together.

Maxwell did the aether model and the math for it.
In the model were the rotational oscillations of massive, compressible
magnetic substance.
The electricity was masless and incompressible.

Now we know that no magnetics substance and that the electricity (electrons)
has mass and that the electron gas is compressible. It means that light is
exactly like sound.

The above was obvious for Royal Society. But the math for the oscillating
whirls was the new.
In result in the science history is wrote "that Maxwell's model was stripped
away and just the equations remain".

The math for whirls was done by Helmholtz but without the oscillations. The
math for the oscillating whirls (EM) must be in schools. In schools are all
theories.

Modern metods are in the plasma physics.
S*

no they aren't... look above, which text did you write and which did i
write?

i used to use outlook express like you are using, and it is bad.  get
something better if you like to quote lots of text.

>  In schools are all theories.

the only purpose for disproved theories in schools is for historical
context.  sometimes it is useful to show students what doesn't work so
they don't waste time repeating past mistakes.  aether theories are
one that is taught and then demonstrated in class as incorrect.  once
the student makes the measurements they get a better feeling why
aethers are bogus.

Hi all

>Walt is not espousing a theory
Please, give me a name to name it.

> They have what is called "internal consistency."
Who are "they", Walter's propositions?

Before advance more Richard. All off you share or ascribe a
"existence" notion determinated by observator measurements? It is long
time philosophical question remember, trees, sounds...

> A confused statement
I know. Communicate minds takes its time. It is more easy as we share
the basic assumptions neccesary for that. It's what I'm trying.

> Two light waves can pass through each other at the same point in space wi=
thout affecting or interacting with each other because they are *not collin=
ear*.

Why? As I learnt superposition principle not depends of collinearity.
English Oxford dictionary I have, define "Interact" as "act on each
other", similar concept in spanish I think. I learnt superposition as
involving 'no interaction'. both waves still identical to itself in
superposition (in nonlineal systems they certainly can interact).

> For pure sinusoidal waves, the transmitted wave, the re-reflected wave, a=
nd the constructive interference wave are all coherent and collinear and me=
rge into a single forward wave flowing toward the load. The component waves=

become inseparable.

I can agree with above paragraph but, for that I just said, I think
not with this...

> Therefore, any two coherent RF waves traveling in the same direction in a=
> n RF transmission line, will interact and have a permanent effect.

As I undestand, two o more superposed waves can be added or
substracted to render a resultant but we do not call that interaction
(I am excude here the observer -Richard's observations- notion for not
to get out of point).
Two traveling waves with same direction, frequency and phase would be
certainly indistinguishable of a single one equal to the vectorial sum
of the two cited, by our instruments. For my conceptual notions adding
or substraction are not interaction. I am not dare to advance more on
your kindly answers because this notions are hardly vinculated to our
issue. Would be appropiate "slow down" a little and work on it?, what
do you think?
.....

About Roy's differences, At two opportunities I read here issues
(problems?) about Rs. Why do not you agree in a simple initial
Thevenin model? (it is a question not a suggestion, I don't know how
correctly translate my sentence).
Cecil, can you find a "energy distribution" concept compatible with
special case of unidirectional line space where all of you can agree?
Transmission/reflection notions (about energy) do not represent that
concept?
A mental exercise (it is doesn't a criticism, only a idea, remember I
am interesed in your analogies): Suppose we are not capable to
perceive any light (or realize of it), only HF spectrum; could you
share (agree?) concepts with our other "blinded" colleagues :>) to
analize this stuff?. I believe that is absolutly a "Yes" (of course
you could use your knowledge in optics to devise good RF arguments,
but you have to silence it, because you know they "antenna senses" are
note light sensitive.
....

> Eugene Hecht, in "Optics", describes standing waves of visible light in f=
> ree space. I'm not sure that humans can "see" the standing wave detail beca=
> use the frequency is so high, but standing waves of visible light can certa=
> inly exist in free space.

In perfect vacuum free space without any material stuff to reflect
light or bring our retinas into the region in some way?
.....

73 to K1TTT. Several years ago I visited your web page, (I have got
them in my hard disk). Sorry to Szczepan for not answer your comments
I hard trying don't run out so much off topic :>)

Hi Miguel,

Walt is presenting data to support a hypothesis (explanation for the occurrence of some specified group of phenomena).

>> They have what is called "internal consistency."
>Who are "they", Walter's propositions?

Models have what is called "internal consistency."

>Before advance more Richard. All off you share or ascribe a
>"existence" notion determinated by observator measurements? It is long
>time philosophical question remember, trees, sounds...

You are getting into intederminancy. Is this more about Truth again?
Truth is funny and sad, but not very useful.

>> A confused statement

>the basic assumptions neccesary for that. It's what I'm trying.
>-------------
>> Two light waves can pass through each other at the same point in space without affecting or interacting with each other because they are *not collinear*.

You don't need "because" or anything that comes after it. It sounds
like superstition.

>Why? As I learnt superposition principle not depends of collinearity.
>English Oxford dictionary I have, define "Interact" as "act on each
>other", similar concept in spanish I think. I learnt superposition as
>involving 'no interaction'. both waves still identical to itself in

Yes.

>> For pure sinusoidal waves, the transmitted wave, the re-reflected wave, and the constructive interference wave are all coherent and collinear and merge into a single forward wave flowing toward the load. The component waves become inseparable.

More superstition. There is nothing about sinusoidal waves that make
them coherent or colinear. This is probable a problem of poor English
from a native speaker - very common.

>I can agree with above paragraph but, for that I just said, I think
>not with this...
>
>> Therefore, any two coherent RF waves traveling in the same direction in an RF transmission line, will interact and have a permanent effect.

Permanent - another superstition (until the end of time + 1 day?).

>As I undestand, two o more superposed waves can be added or
>substracted to render a resultant but we do not call that interaction
>(I am excude here the observer -Richard's observations- notion for not

They interact on the load, not on each other. But as you now phrase it, being colinear as an initial condition rather than as a subsequent result, then the possibility of both sources (acting as opposing loads) cancelling each other may follow.

This says nothing of waves interacting, however. That is sheer nonsense.

Let's put it another way and agree entirely! Accept that two coherent waves that are colinear do interact - but only if colinear. That must be some very, very special mathematics that allows no error in colinearity (perfection is demanded). Perfection does not exist, the necessary colinearity does not exist, interaction does not exist.

OK, so near perfection is suitable. -sigh- How much is "near perfection?" Within one millirad? What is it about 1.000001 millirad that extinguishes interaction? Oh, 1.000001 millirad works too, but not more. OK, what is it about 1.000002 millirad that extinguishes interaction? Oh, 1.000002 works too, but.... Pretty sloppy argument, I don't see a formula for when interaction stops working, this means that all angles cause interaction, but we do not see interaction at any angles.

This "take it on faith" kind of creation (create it as you go) science returns us to vaudeville (Miguel, maybe I should use the term Commedia dell'Arte to explain our vaudeville).

"God said let there be a photon... go forth and multiply"
     [- low budget creation science definition
     for the Sun(s) taken from the first printing of
     "How to Kick Start Genesis on One Quanta a Day."]

(Adam, muttering) what a day.... what a day.... (suddenly inspired) What a beautiful photon-set we are having this, this, this. I think I shall name this "evening" Eve! What a beautiful photon-se.... Damn! (whoops - oh I beseech thee to forgive my utterance) it got dark quick. How long before photon-rise? Are we on photon savings time?

>Suppose we are not capable to

Richard-

I have a steel well pipe that is approximately a quarter wave on 40
Meters.  Even though it is buried, why wouldn't this work as the bottom
half of a vertical dipole?

I tried it with a mobile whip as the vertical element.  It worked better
than I expected, but not really well.

Hi Fred,

One perspective of the radial field is that it shields the radiator from the loss of ground. However, that simplification disguises the fact that the radials radiate too - and unproductively. When every radial's radiation is taken into consideration, opposite radials (each one that is 180 degrees from the other) cancel.

That aside, their benefit is they conduct better than dirt. What this means is more power goes into copper/steel instead.

Now, if we consider your well pipe, it goes deeper into that lossy dirt and the deeper it goes, the more dirt the return signal (to the other, the vertical radiator) has to go through. More loss than use.

OK, another reason. For as poor/well as dirt may conduct, it too has skin effect. This means at some distance into the dirt, conductivity plummets because of skin effect. Deeper yet, and the skin effect loss increases at a quick clip.

As skin effect is frequency dependent, at really low frequencies, your well pipe has some advantage. This frequency range is suitable for working lightning whose top end is 1MHz. At 7 MHz, there's no point.

>I tried it with a mobile whip as the vertical element. It worked better
>than I expected, but not really well.

Which shows you how crummy the whip is because what well pipe there was that was above ground was doing the job of the whip.

Step back and look at the big picture using your analogy of a vertical dipole with half of it buried. Now, convert that buried half into multistrand. Bend each strand 90 degrees so that each strand just rides an inch or two above ground with all of the newly bent strands in a flat circular spray around the upper half. Walla! as the French say.

I am not out of topics. It is to your:
"To concentrate light we only need a piece of glass, to do the same on
HF RF region we need large wire antenna arrays. Because of this we
often need (or employ) very differents models to deal with the "same
thing". Probably Maxwell equations solve all of them, but they are
difficult ladies to deal :>)."

You should read the Maxwell:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
Maxwell described the model in English and in the math. English is not
difficult ladies to deal for you.

After this you understand why: "that Maxwell's model was stripped away and
just the equations remain".
Light and radio waves are exactly like sound.
S*

```

how about this, i'll really mess things up. all comments assume linear media or circuit elements and sinusoidal stead state conditions (all transients ignored).

Standing Waves are a figment of your instrumentation... it is a well known method to choose either voltage or current to do calculations in a circuit, knowing that the other can always be calculated given the impedance. this works for distributed as well as lumped circuits. it is a consequence of superposition and ohms law in the generalized complex form. This is a trap when looking at traveling and 'standing' waves when there are reflections. Since you are only seeing one of the components of the wave you get the impression that the standing wave is indeed concentrating the energy and all the resultant effects at 180 degree intervals. you must however look at both components to get a full picture.

Wherever there are standing voltage wave peaks there are also standing current waves 90 degrees (in distance) along the line from them. And while you can calculate the power of the voltage wave peaks as V^2/Z, you can also calculate the energy of the current wave peaks as I^2*Z. Of course you can really get yourself confused if you consider the lossless transmission line with a perfect short or open end... in that case at those peak voltage and current points the Z is infinite or zero respectively which gives you zero power in either case. Now to REALLY have fun, integrate the power at those points into the energy, of course the integral of zero is always zero.

Want to get even more confused. Look at an animation of the standing waves (EITHER current OR voltage) over one full cycle in time, there is a peak where the standing waves along the line all reach a peak value at once, then 90 degrees later the whole line is zero, then another 90 degrees and there is an opposite peak. Think carefully about the zero point, where did the energy go? Surely it doesn't mean that all the energy stored in those waves has left the line? that would require some external storage and faster than light energy transfer, a mean trick if you can do it!

Ah, but wait, the current wave is 90 degrees out of phase with the voltage, so the energy has a place to go, into the other component! but remember, when that component peaks the impedance is wrong so there is still no energy. But of course then everything does balance out, no energy in one standing wave transfers perfectly to the other standing wave 90 degrees later in time and space.

conclusion: Standing waves are a figment of your instrumentation, be that eyes seeing the peaks and valleys of a physical manifestation of them, a fluorescent lamp showing them as you run it along an open wire line, or a voltmeter measuring them... they don't exist except when they are observed, therefore they have no physical existence... much like whats his name's cat.

On May 30, 9:04=A0pm, Richard Clark <kb7...@comcast.net> wrote:

> There is nothing about sinusoidal waves that make
> them coherent or colinear.

Please Google the two words: I probably should have use "collimated"
instead of "collinear".

"Electromagnetic radiation is coherent when the photons are produced
in such a way that they are in phase with one another and incoherent
when the phases of the photons are random."

"Collimated light is light whose rays are nearly parallel, and
therefore will spread slowly as it propagates. The word is related to
"colinear" and implies light that does not disperse with distance
(ideally), or that will disperse minimally (in reality)." Note that a
coaxial transmission line results in minimal dispersion for an RF
wave.

Coherent photons are identical except for direction. Collimation makes
their direction close to identical.

> Permanent - another superstition (until the end of time + 1 day?).

Wrong definition of "permanent". Not permanent in time - permanent in
the sense that the process is irreversible in time.

> > As I undestand, two o more superposed waves can be added or

> >substracted to render a resultant but we do not call that interaction

We do call it interaction when the two waves are coherent and collimated. Again, here is what Florida State University has to say:

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the photon energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so the effect should be considered as a redistribution of light waves and photon energy rather than the spontaneous construction or destruction of light."

They are talking about wave cancellation such that happens at the surface of the thin-film on non-reflective glass. The result of wave cancellation is permanent and the energy that would have been reflected is reversed in direction actually making the underlying picture brighter. That sounds permanent to me.

> They interact on the load, not on each other.

If that were a fact, you could separate them on their way to the load but such is impossible. It doesn't matter where they came from, two coherent, collimated waves interact when they are superposed and become inseparable from that point on. Only incoherent or uncollimated photonic waves can be separated.

And if you allow interaction at the load, why not allow interaction at an impedance discontinuity which is much like a load and is indeed where the interaction happens.

> This says nothing of waves interacting, however. =A0That is sheer
> nonsense.

Wave cancellation is an obvious proof of interaction. Let's see you recover two waves that have been canceled.

> Let's put it another way and agree entirely! =A0Accept that two coherent

> be some very, very special mathematics that allows no error in
> colinearity (perfection is demanded). =A0Perfection does not exist, the
> necessary colinearity does not exist, interaction does not exist.

"Perfection does not exist" is the self-fullfilling last gasp non-perfect argument of the ignorant. Close enough to collimation perfection does exist in an RF transmission line or in an interferometer. The coherent photons in an ideal coaxial transmission line are forced into a state of collimation. Is it perfect single-file collimation? Of course not, but it doesn't have to be perfect. Confining the photons to a certain cross-sectional area is all that is required in the real world. Do all the photons have to be perfectly coherent? No, just the majority of photons from the transmitter.

Does a 1/4WL non-reflective coating on glass perfectly cancel 100$ of the single-frequency coherent incident laser light? Not in the real world, but you can use your own eyes to detect that it is doing a pretty good job. The Melles-Groit web page says:

"In the absence of absorption or scatter, the principle of conservation of energy indicates all 'lost' reflected intensity will appear as enhanced intensity in the (forward) transmitted beam. The sum of the reflected and transmitted beam intensities is always equal to the incident intensity. This important fact has been confirmed experimentally."

Those above alluded-to experiments seem to contradict what you are asserting. Do your own experiments disprove what that web page is saying? If so, where did they go wrong?

On May 30, 7:28=A0pm, lu6etj <lu6...@gmail.com> wrote:

Miguel, please see my above posting in reply to Richard's posting.

> As I learned, the superposition principle does not depend on collinearity=
> .

Please change "collinear" to "collimated". The results of superposition can be reversible or irreversible. If the photons are not coherent and/or not collimated, the results of superposition are reversible in the sense that each separate wave can be recovered. The results of superposition of coherent and collimated waves (traveling in the same direction) are not reversible, i.e. the ability to recover the separate waves has been lost forever. Two coherent/collimated waves that are superposed indeed do interact. Non-reflective glass is a typical example. The external reflection interacts with the internal reflection causing the reflections to undergo wave cancellation and the total energy in the two superposed (canceled) waves to change direction and make the picture brighter. The Melles-Groit web page says:

"This important fact has been confirmed experimentally."

> As I understand, two or more superposed waves can be added or
> subtracted to render a resultant but we do not call that interaction.

I call it interaction when the identity of both waves is lost which is what happens during wave cancellation. It is not interaction when the identity of both waves is not lost. The results of superposition can have either outcome.

> For my conceptual notions adding or subtraction are not interaction.

If you add a pint of water to a pint of water, the two pints of identical molecules interact, analogous to one joule of coherent/ collimated photons added to another joule of the *identical* photons. The results is two joules of identical photons, indistinguishable from each other. If the superposition process is reversible, interaction has not taken place. If the superposition process is irreversible, interaction has taken place. Both outcomes are possible depending upon the initial conditions.

> Why do not you agree in a simple initial Thevenin model?

It was Roy's idea to avoid the abstract Thevenin model and go with a similar real-world source, probably because of the admonition in "Fields and Waves ...": "... significance cannot be automatically attached to a calculation of power loss in the internal impedance of the equivalent circuit."

> Transmission/reflection notions (about energy) do not represent that
> concept?

The mistake that virtually all RF gurus are making, including w7el in his food-for-thought article, is assuming that reflection is the only mechanism capable of redistributing reflected energy back toward the load. But it has been known for decades in the field of optical physics that EM wave cancellation can also redistribute reflected energy back toward the load. It is well known that the reflected energy lost through the use of non-reflective glass causes the picture (load) to be brighter. If w7el would simply take the time to calculate the wave cancellation energy (constructive or destructive interference) at the source resistor, he would understand exactly where the reflected energy goes. The conservation of energy principle allows nothing magic (like reflected waves containing no energy or EM waves that do not move at the speed of light).

> Suppose we are not capable to
> perceive any light (or realize of it), only HF spectrum; could you
> share (agree?) concepts with our other "blinded" colleagues =A0:>) to
> analize this stuff?

It is very useful to say: If our eyes could see the RF waves, what would we see? We would see the same thing we see with visible light waves, just at a different frequency (wavelength).

> In perfect vacuum free space without any material stuff to reflect
> light or bring our retinas into the region in some way?

Of course, we would need some sort of irradiance detector more sensitive than human retinas. Partially mirrored glass is often used to route a sample to a detector. If we detect standing waves in a 10% sample, we are pretty sure that standing waves exist in the rest of

```
the sample.

I would say: Standing waves are a virtual image caused by the two
traveling waves (forward and reverse). I wonder if we could see a

visible light standing wave in a cloud chamber if we used a
microscope?

ah, but in this case consider that you have a pint of blue water moving to the right and a pint of red water moving to the left to be a better analogy to currents of the waves moving forward and backward in the coax. there are then 3 possibilities:

1. the two mix and cancel giving you 2 pints of purple water not going anywhere.
2. the two bounce off of each other now giving you red water moving right and blue water moving left.
3. the two pass by each other not mixing at all and continue on their way.

if 1 happened you would indeed cancel the waves and end up with a spare pile of electrons not going anywhere. while this may be adequate for a mechanical analogy it doesn't say where the energy of those two moving pints went so is obviously wrong.

number 2 conserves energy at least.

number 3 also conserves energy and gives the same energy distribution as 2.

since electrons aren't colored it makes number 2 and 3 indistinguishable, so clearly the result is that both waves continue on their way undisturbed by the other... which is what is observed in all cases of em wave interaction in linear media.

no need, just look at the lines on a hologram, that is the map of the
interference patterns from the reflected and reference laser beams.

No, no, no. I am NOT talking about forward and reflected waves moving in opposite directions. I am talking about two coherent, collimated waves *MOVING IN THE SAME DIRECTION* in an RF transmission line away from an impedance discontinuity - either two waves moving forward toward the load or two waves moving backwards in the opposite direction toward the source. Such multiple wavefronts occur at impedance discontinuities because of multiple reflections.

Forward and reflected waves (waves moving in opposite directions in a constant Z0 environment) do NOT interact. At an impedance discontinuity, the component reflections and transmissive waves do interact if they are coherent, collimated, and MOVING IN THE SAME DIRECTION.

Oh yeah, duh ... brain fart - if one slants the partial mirror
detector, one can spread the interference patterns out to an optimum
pattern for viewing by a human eye.

Miguel, I want you to note how David clearly exposes the failure of a metaphor, using the metaphor's own analogy.

This is the danger of trying to explain one system in terms of another without knowing how either work.

It also reveals in shades of deep purple, how the visual system lies to us, and we believe we see the Truth.

So, for metaphors and analogies, when the reader knows better, its a lark (an amusing adventure or escapade); or when the writer knows better, its a lark (behavior in a mischievous way).

If you both don't know better, its a lark (activity regarded as foolish or a waste of time by the rest of us).

Carefully parse the following:
"Truth is a lark."

73's
Richard Clark, KB7QHC

Hi Richard. thanks for your reply.

I recognize so much the Walter's work as I said in my initial post.
"Another look at reflections" was one of the my most appreciated
readings of my early days as student and Ham.
But without wishing to be flattering ("adulador" in spanish), I feel
in debt with much others works from you (all) (I do not give more
names to not commit injustice omiting anyone).
I believe you are a gifted, brilliant, intelligent and supportive Hams
sharing your knowledge and experience with us. For that, I am/we are
indebted to all of you :>)

However, I believe for all reasons given above, you will be capable to
arrive to a good technical/scientific consensus about the matter. We
trust in your ability and capacity to get it.
This is very important for us because not all are capable to develop
theory from empirical working and we need your agreement to study
things that in my experience are very difficult to grasp even for

university graduates...

Keith,

Assertions have been made about the Thevenin equivalent source impedance (Zs) of an RF PA. In the discussions over the years, some people have imposed some qualifications (eg classes, tuned / untuned etc).

Zs can be measured by a number of methods. It is interesting to note that in many of the discussions on the 'net on this topic, more focus is given to dismissing the experiment design for experiments that produce unfavourable results to some, than questioning the proposition that Zs is 50+j0 or thereabouts.

Whilst Walt has documented a quite rigourous experiment, and it produced a favourable outcome, it is my view that that in itself is not proof of the proposition.

Whilst one favourable experiment cannot proove the proposition correct, just one valid experiment can prove the proposition to be not generally true. No doubt the reason for the focus on proving experiments invalid.

If you give some thought to what you could use Zs for, then every valid experiment that is designed around that application must produce a favourable outcome if Zs is as proposed. If they don't, then the value assumed for Zs must be wrong.

I posted a simple test earlier that in my experience does not support the proposition that typical ham HF transmitters have Zs=50+j0 or close to it. The test is documented so that individuals can try it and make their own mind up. Some might get favourable results on limited trials... but in my view, that is outweighed by unfavourable results from valid experiments.

Owen

Hi, Folks.

Looking for some advice.

I want to create a grounded opening in the wall of my ham shack through which I'll install each rf cable that enters the shack. I plan to bolt a conductive plate to the wall ground that I'll fasten the ground side of each coaxial cable to, then bolt a ground cable to each ground rod and the plate.

Is there a significant difference between using the galvanized steel ground rods and copper to create an rf gound? The copper ones are more than double the price - is it worth using them?

Thanks, Bob, VE7HS

Hi Miguel,

A nice sentiment, but even the most silvered authorities disagree. One
has only to look at the relativist camp vs. the quantum camp in
nuclear physics.

>This is very important for us because not all are capable to develop
>theory from empirical working and we need your agreement to study
>things that in my experience are very difficult to grasp even for
>university graduates...

Then, this will be dissappointing. University is for finding your own
way, and that does not come without regrets. There's a maxim that
applies here:
"If you haven't failed, you are not trying hard enough."

Now just hold on right there!
As I have stated before, wave is a descriptive word
and not a noun as described by a particle. Just as a
amount of moisture does not become equal to a cloud. You are using
existing positions and theories
without the required accompanying proof
The truth is that none of the existing theories stand up to
examination to explain the phenomina of radiation upto and including
the super string theory.
Thus they are all suspect in one way or another.
Right at the very beginning I used Gauss's definition to describe a
particle, no where is the term wave mentioned Now we come to Maxwells
equations he also does not mention waves because he is considering a
instant of time which includes every function required to perform the
function of displacement of a particle as refferred to by Gauss. He
also reinforced the idea of equilibrium per Newtons laws by assuring
that all components involved in the equation equalled zero.
Thus one can say using long existant rules that what is made dynamic
must also be resonant and where the sum is in equilibrium. Now all the
expressions you are using comes from discredited theories, where as
mine comes from the existance of the Newtons boundary rules, gaussian
postulate and and the combination of many inputs from the masters of
that time that provided Maxwells laws.
I am just using the existing classical rules of the day
nothing is new and there is no reinvention of any kind.
So I put it to you again that it unreasonable to quote

hypothesis that have been proved not up to the task
and to not provide supporting reason to discredit Maxwell,Gauss and
the other masters on whose shoulders we stand on today. Forget about
your beloved photons which you habitually use as a shell game to
confuse onlookers and review which is considered correct up to "this
particular point" instead of making giant hops up the ladder of
knowledge like jumping the Grand canyon in two jumps. If you have good
reason to diss the work of the masters then I am sure others will want
to hear about it.
Best regards, nothing personal intended

Yes Richard. I agree, however I said "even for graduated" ("a=FAn para
graduados" in spanish), but this a radio Amateur group, isn't it...
Hey Richard, do not be hard with us :>) your helping is important and
valuable for hundred (if not thousands) of present an future Amateurs.
Thanks again.

Miguel

May we advance in little steps to ensure we share basic assumptions?

1) I did not think of (or is think on?) a laser source, I was one step
before, I think only of a "coherent" source to match monofrequency
simple AC generator analogy.
2) What would be Rs optical analog?
3) Superposition is a medium phenomenon =BFyes?, for example "eter".

Interference an result of it on a other "thing", for example
photographic plate or screen. Are we agree? K

>
> Whilst one favourable experiment cannot proove the proposition correct, just one valid experiment can prove the proposition to be not generally true. No doubt the reason for the focus on proving experiments invalid.
>
> If you give some thought to what you could use Zs for, then every valid experiment that is designed around that application must produce a favourable outcome if Zs is as proposed. If they don't, then the value assumed for Zs must be wrong.
>
> I posted a simple test earlier that in my experience does not support the proposition that typical ham HF transmitters have Zs=3D50+j0 or close to it. The test is documented so that individuals can try it and make their own mind up. Some might get favourable results on limited trials... but in my view, that is outweighed by unfavourable results from valid experiments.
>
> Owen

Owen, I have reviewed your simple test using an ATU to obtain various load impedances, but I don't see any data showing the results of any tests you may have made using this procedure. I'm assuming it's the same procedure I used in measuring the data I presented in Chapter 19 of Reflections 2, in which I varied the load impedance by switching between two different, but closely related values of load resistance.

Unless we're discussing RF power amps using solid-state components, I don't understand why anyone would expect the source impedance to be 50

+ j0 ohms unless the source was delivering all its available power into a 50 + j0 load.

I've made an addition to Chapter 19 as it appears in Reflections 2. That addition now appears in the new edition, Reflections 3. In that addition I report the procedure and results of measuring the output impedance of a Kenwood TS-830S terminated in a complex load of 17.98 + j8.77 ohms. I described fourteen steps in the procedure that resulted in the measured output impedance of the Kenwood to be 18 - j8 ohms, which is sufficiently close to the conjugate of the load to be a practical conjugate match between the source and load impedances.

Why then do you discount the data from my measurements as not proof that the 18 - j8 ohms of source impedance is valid?

I'm going to try to insert a copy of the 14 steps of the procedure. However, as I have tried this type of insertion previously and failed, it also may fail here. If it fails I invite you to go to my web page at www.w2du.com and click on the line "Preview Chapters from Reflections 3" and then click on Chapter 19A, then scroll down to Sec 19A.5 Additional Experimental Data. There you will see the detailed description of the entire procedure. I hope this will help in understanding my posistion concerning the measurement of the source impedance at the output of the tank circuit of an RF power amplifier.

Sec 19.14 Additional Experimental Data

The source resistance data reported in Secs 19.8 and 19.9 were obtained using the load variation method with resistive loads. Note that of the six measurements of output source resistance reported in Table 19.1, the average value of the resistance is 50.3 ohms obtained with the reference load resistance of 51.2 ohms, exhibiting an error of only 1.8 percent. However, various critics assert that proof of a conjugate match between the source and load requires the load to contain reactance. Accordingly, the experimental data reported below were obtained using both the load variation method and an indirect method for determining the source impedance of the RF power amplifier, with a resistive load to obtain a reference source resistance and a complex load to determine the complex source impedance that is then proven to be the conjugate of the complex load.

We=E2=80=99ll now examine the experimental data that resulted from measurements performed subsequent to those reported in Secs 19.8 and 19.9, new data that provides additional evidence that a conjugate match exists at the output terminals of an RF power amplifier when all of its available power is delivered into its load, however complex the load impedance. According to the definition of the conjugate match as explained in Sec 19.1, Axioms 1 and 2, if this condition prevails there is a conjugate match. In addition, the data presented below also provides further evidence that the output source resistance of the RF amplifier is non-dissipative. The following steps describe the experimental procedure I employed and the results obtained:

1. Using a Kenwood TS-830S transceiver as the RF source, the tuning

and loading of the pi-network are adjusted to deliver all the available power into a 50 + j0-ohm load with the grid drive adjusted to deliver the maximum of 100 watts at 4 MHz, thus establishing the area of the RF power window at the input of the pi-network, resistance RLP at the plate, and the slope of the load line. The output source resistance of the amplifier in this condition will later be shown to be 50 ohms. In this condition the DC plate voltage is 800 v and plate current is 260 ma. DC input power is therefore 800 v =EF=82=B4 0.26 a =3D 2=
08 w.
Readings on the Bird 43 wattmeter indicate 100 watts forward and zero watts reflected. (100 watts is the maximum RF output power available at this drive level.) From here on the grid drive is left undisturbed, and the pi-network controls are left undisturbed until Step 10.

2. The amplifier is now powered down and the load resistance RL is measured across the input terminals of the resonant pi-network tank circuit (from plate to ground) with an HP-4815 Vector Impedance Meter. The resistance is found to be approximately 1400 ohms. Because the amplifier was adjusted to deliver the maximum available power of 100 watts prior to the resistance measurement, the averaged resistance RLP looking into the plate (upstream from the network terminals) is also approximately 1400 ohms. Accordingly, a non-reactive 1400-ohm resistor is now connected across the input terminals of the pi-network tank circuit and source resistance ROS is measured looking rearward into the output terminals of the network. Resistance ROS was found to be 50 ohms.

3. Three 50-ohm dummy loads (a 1500w Bird and two Heathkit Cantennas) are now connected in parallel to provide a purely resistive load of 16.67 ohms, and used to terminate a coax of 13.5=C2=B0 length at 4 MHz.

4. The impedance ZIN appearing at the input of the 13.5=C2=B0 length of coax at 4 MHz terminated by the 16.67-ohm resistor of Step 3 is measured with the Vector Impedance Meter, and found to be 20 ohms at =EF=83=
=90
+26=C2=B0. Converting from polar to rectangular notation, ZIN =3D 17.98 + j8.77 ohms. (ZIN =3D ZLOAD from the earlier paragraphs.) This impedance is used in Steps 5 and 6 to provide the alternate load impedance in the load-variation method for determining the complex output impedance of the amplifier, and for proving that the conjugate match exists.

5. With respect to 50 ohms, ZIN from Step 4 yields a 2.88:1 mismatch and a voltage reflection coefficient rho =3D 0.484. Therefore, power reflection coefficient rho^2 =3D 0.235, transmission coefficient (1 =E2=80=
=93
rho^2) =3D 0.766, and forward power increase factor 1/(1 =E2=80=93 rho^2) =
=3D
1/0.766 =3D 1.306.

6. Leaving pi-network and drive level adjustments undisturbed, the 50-ohm load is now replaced with the coax terminated with the 16.67-ohm load from Step 4, thus changing the load impedance from 50 + j0 ohms to 17.98 + j8.77 ohms, the input impedance ZIN of the coax.

7. Due to the 2.88:1 mismatch at the load, neglecting network losses
and the small change in plate current resulting from the mismatch,
approximately the same mismatch appears between RLP and ZL at the
input of the pi-network. Consequently, the change in load impedance
changed the network input resistance RL from 1400 ohms to complex ZL =3D
800 =E2=80=93 j1000 ohms, measured with the Vector Impedance Meter using th=
e
method described in Step 2. To verify the impedance measurement of ZL
the phase delay of the network was measured using an HP-8405 Vector
Voltmeter and found to be 127=C2=B0. Using this value of phase delay the
input impedance ZL was calculated using two different methods; one
yielding 792 =E2=80=93 j1003 ohms, the other yielding 794.6 =E2=80=93 j961.=
3 ohms,
thus verifying the accuracy of the measurement. However, although grid
voltage EC, grid drive EG, are left unchanged, resistance RLP of
approximately 1400 ohms at the plate has changed somewhat due to the
small changes in plate voltage and plate current due to the change in
the load, leaving a mismatch between RLP and ZL at the input of the pi-
network. As stated above, this value of ZL yields the substantially
the same mismatch to plate resistance RLP as that between the output
impedance of the pi-network and the 17.98 + j8.77-ohm load, i.e.,
2.88:1. This mismatch at the network input results in less power
delivered into the network, and thus to the load, a decrease in the
area of the RF window at the network input, and a change in the slope
of the loadline. (It must be remembered that the input and output
mismatches contribute only to mismatch loss, which does not result in
power delivered and then lost somewhere in dissipation. As we will see
in Step 8, the mismatch at the input of the pi-network results only in
a reduced delivery of source power proportional to the degree of
mismatch.)

8. Readings on a Bird 43 power meter now indicate 95w forward and 20w
reflected, meaning only 75 watts are now delivered by the source and
absorbed in the mismatched load. The 20w reflected power remains in
the coax, and adds to the 75 watts delivered by the source to
establish the total forward power of 95w.

9. We now compare the measured power delivered with the calculated
power, using the power transmission coefficient, 1 =E2=80=93 rho^2. The
calculated power delivered is: 100w x (1 =E2=80=93 rho^2) =3D 76.6w, compar=
ed to
the 75w indicated by the Bird wattmeter. However, because the new
load impedance is less than the original 50 ohms, and also reactive,
the amplifier is now overloaded and the pi-network is detuned from
resonance. Consequently, the plate current has increased from 260 to
290 ma, plate voltage has dropped to 760 v, and DC input power has
increased from 208 w to 220.4 w.

10. With the 17.98 + j8.77-ohm load still connected, the pi-network
loading and tuning are now re-adjusted to again deliver all available
power with drive level setting still left undisturbed. The
readjustment of the plate tuning capacitor has increased the

capacitive reactance in the pi-network by =E2=80=938.77 ohms, canceling the +8.77 ohms of inductive reactance in the load, returning the system to resonance. The readjustment of the loading control capacitor has decreased the output capacitive reactance, thus reducing the output resistance from 50 to 17.98 ohms. Thus the network readjustments have decreased the output impedance from 50 + j0 to 17.98 =E2=80=93 j 8.77 ohms, the conjugate of the load impedance, 17.98 + j8.77 ohms. The readjustments have also returned the network input impedance ZL to 1400 + j0 ohms (again equal to RLP), have returned the original area of the RF window at the network input, and have returned the slope of the loadline to its original value. For verification of the 1400-ohm network input resistance after the readjustment, ZL was again measured using the method described in Step 2, and found it to have returned to 1400 + j0 ohms.

11. Bird 43 power meter readings following the readjustment procedure now indicate 130w forward and 29.5w reflected, indicating 100.5w delivered to the mismatched load.

12. For comparison, the calculated power values are: Forward power =3D 100 x 1.306 =3D 130.6w, reflected power =3D 30.6w, and delivered power =3D 130.6w =E2=80=93 30.6w =3D 100w showing substantial agreement with the meas= ured
values. (1.306 is the forward power increase factor determined in Step 5.) Plate current has returned to its original value, 260 ma, and likewise, plate voltage has also returned to the original value, 800 v. Consequently, the DC input power has also returned to its original value, 208 w.

13. It is thus evident that the amplifier has returned to delivering the original power, 100 watts into the previously mismatched complex-impedance load, now conjugately matched, the same as when it was delivering 100 watts into the 50-ohm non-reactive load. But the reflected power, 30.6 watts, remains in the coax, adding to the 100 watts delivered by the amplifier to establish the 130.6 watts of forward power, proving that it does not enter the amplifier to dissipate and heat the network or the tube.

It must be kept in mind that impedance ZIN appearing at the input of the 13=C2=B0 line connecting the 16.7-ohm termination to the output of the amplifier is the result of reflected waves of both voltage and current, and thus reflected power is returning to the input of the line, and becomes incident on the output of the amplifier.

The significance of these measurement data is that for the amplifier to deliver all of its available power (100w) into the mismatched load impedance ZIN =3D 17.98 + j8.77 ohms, the readjustment of the tuning and loading of the pi-network simply changed the output impedance of the network from 50 + j0 ohms to 17.98 =E2=80=93 j8.77 ohms, t= he
conjugate of the load impedance, thus matching the output impedance of the network to the input impedance of the coax. Consequently, there is a conjugate match between the output of the transceiver and its complex load. QED. The readjustments of the pi-network simply changed

its impedance transformation ratio from 50:1400 to (17.98 =E2=80=93 j8.77): 1400, returning the input resistance RL of the pi-network to 1400 ohms, the value of RLP. Thus the plates of the amplifier tubes are unaware of the change in external load impedance.

14. We=E2=80=99ll now make an additional indirect measurement of ROS t=hat proves the conjugate match statement above is true. Leaving the pi-network adjustments undisturbed from the conditions in Step 10, with the amplifier powered down we again connect a 1400-ohm non-reactive resistor across the input terminals of the pi-network tank circuit and measure impedance ZOS looking rearward into the output terminals of the network. The impedance was found to be ZOS =3D 18 =E2=80=93 j8 ohms.

From a practical viewpoint, measured impedance ZOS =3D 18 =E2=80=93 j8= ohms is the conjugate of load impedance ZLOAD =3D 17.98 + j8.77, proving that the amplifier is conjugately matched to the load, and also proving the validity of the indirect method in determining that the source impedance of the amplifier is the conjugate of the load impedance when all available power is being delivered to the load.

Thus the data obtained in performing Steps 1 through 14 above proves the following four conditions to be true:

No reflected power incident on the output of the amplifier is absorbed or dissipated in the amplifier, because:

1. The total DC input power is the same whether the amplifier is loaded to match the resistive Z0 load of 50 + j0 ohms, with no reflected power, or to match the complex load of 17.98 =E2=80=93 j8.77 ohms with 30.6 watts of reflected power, while 100 w is delivered to either the Z0 load or the re-matched complex load.

2. All the 100 watts of power delivered by the transmitter is absorbed in both the Z0 load and the re-matched complex load cases, with the same DC input power in both cases.

3. All the 30 watts of reflected power has been shown to add to the source power, establishing the total 130 watts of forward power in the case involving the re-matched complex load.

4. All the reflected power is added to the source power by re-reflection from the non-dissipative output source resistance ROS of the amplifier. Had the output source resistance of the amplifier been dissipative the reflected power would have been dissipated there into heat, instead of being re-reflected back into the line and adding to the source power. In addition, the Bird 43 power meter would have indicated 75 watts of forward power, not 95. This proves that reflected power incident on the output of the amplifier does not cause heating of the tube.

It should also be noted, an accepted alternative to the load-variation method for measuring the output impedance of a source of RF power is the indirect method demonstrated above. As performed during the measurements described above, the procedure for this method is to first make the necessary loading adjustments of the output network to ensure that all of the available power is being delivered to the load. Next, the input impedance of the load is measured. It then follows that, as proven above, the source impedance is the conjugate of the input impedance measured at the input of the load, because when all available power is being delivered to the load, this condition conforms to the Conjugate Matching and the Maximum Power-transfer Theorems17.

Additionally, I previously performed this same measurement procedure using a HeathKit HW-100 transceiver, using several different lengths of coax between the 16.7-ohm load and the output of the transceiver in each of several measurements. The different lengths of coax provided different complex load impedances for the transceiver during each measurement. The same performance as described above resulted with each different load impedance, providing further evidence that a conjugate match exists when the amplifier is delivering all of its available power into its load. These results also prove that the single test with the Kenwood transceiver is not simply a coincidence.

Walt, W2DU

EME operators, who have the greatest need of pattern control, noise
temperature and efficiency, would not agree.  They use the T match.

Hi Bob,

Two answers for that:
1. No difference whatever;
B. Neither make an RF ground.

Updates will follow this brief announcement.

Oops. You are talking about just a dipole, so the above doesn't really
apply.

And neither does any worries about skew. If it skews on a dipole who
cares? Just turn it, if you can even tell it skewed.

Hi Owen,

Even this Zs = 50+j0 or thereabouts is a distraction. Quite simply, being able to reject a single value is an evasion of facing the evidence of source resistance.

What is more comic is both sides couldn't agree more! Truly Kabuki.

>Whilst Walt has documented a quite rigourous experiment, and it produced
>a favourable outcome, it is my view that that in itself is not proof of
>the proposition.

Propositions seem to abound as n+1 the number of participants. I dare say no two participants can agree what any single proposition is without adorning further distractions to it like bulbs on a Christmas tree.

>Whilst one favourable experiment cannot proove the proposition correct,
>just one valid experiment can prove the proposition to be not generally
>true. No doubt the reason for the focus on proving experiments invalid.

Proving a straw man invalid is simple. Proving a murky proposition invalid is simple too. Unfortunately, the occurrences of actually stepping up to the bench and showing results other and conclusively different from those offered is a void in the discussion.

It would seem the qualitative counter-proof comes cheap and that submitted quantifiables are unchallenged. Quite a paradox.

>If you give some thought to what you could use Zs for, then every valid
>experiment that is designed around that application must produce a
>favourable outcome if Zs is as proposed. If they don't, then the value
>assumed for Zs must be wrong.

>it. The test is documented so that individuals can try it and make their
>own mind up. Some might get favourable results on limited trials... but
>in my view, that is outweighed by unfavourable results from valid

>experiments.

For years I have read that Zs is not ____. Just as quantifiables are brushed off the table of discussion, I have yet to see measure of what the objectors' Zs IS instead under any circumstance that they can conveniently arrange with their own tools and source.

It is a tautology that if it is not X, it must be Y, or Z, or.... None seem to know an explicit answer under any circumstance or configuration of their own gear. Without some value such as 10 Ohms, 50 Ohms, 10,000 Ohms, it leaves a most curious happenstance that any garden variety ham transmitter exhibits either 0 or infinite source resistance - but I dare say no one is going to step forward to accept these boundary limits either!

No counter-proclaimants of ANY value between and including 0 to infinity. It would be a commitment anyone could validate or refute on the basis of science at the bench - and what would follow from that examination? I would find such discussion refreshing in comparison.

What a happy state of ignorance this topic draws out of the wallpaper.

>> > As I have stated before, wave is a descriptive word
>> > and not a noun

Let's see where the descriptive wave (not a noun) leads us.
Wave-and-go cashcard: contactless payment system.
Wave aquatics: a competitive swim program.
Wave church: "we invite you to be a part of Wave Women."
Wave dash: a technique in Melee that causes a character to slide along the ground without walking or running.
Wave extension: hair, also called a "fall."
Wave grease: more hair, control pomade.
Wavey gravy: psychedelic sauce.
Wave hook: antenna.
Wave iron: even more hair, for curling.
Wave jumper: a boat.
Wave keyboard: what you type on if you are really kewel.
Wave machine: something one would find at a water park.
Wave meter: a tunable cavity with a frequency scale.
Wave scholarship: The Washington Award for Vocational Excellence.
and probably some more.

Which one is being talked about?

Maxwell's math from any date describes the Maxwell hipothesis on massive
magnetic whirl.

>, and even the publication of
gauss' law... so much development was done in em theories after that
date.

"EM theory" was stripped away by scientists and anybody developed it.
All works with electrons.

Heaviside who wrote the set of "maxwell's equations" was an engineer.
Teachers adopt the equations to teach the match.

> just because something is written down doesn't make it right or
we would still be living with 4 elements and letting blood to cure
disease.

The magnetic substance do not exists but you still are living with it.

In space is plasma (ions and electrons) and dust. That all rotate with the
Sun.

OK, good example. Cataracts presents absorption, transmission and reflection (they are whitish). To be analog I think should not have reflection. What do you think? (Perhaps seems maieutics but really I am trying to put my thoughts in order at first).

What about the third point? I consider it important because light waves are in three dimensional space, so when they cancels in a region, reinforces in other and I can understand redistribution, but line travelling waves are in unidimensional space and here I can not visualize (realize?) the energy redistribution as in light interference. Sorry, when I put interrogation words inside parentheses is that I am not sure the better/adecuated translation.

Sorry I thought it was a very simple Cecil's answer.  It was a joke,
wasn't it?. It is my fault... I did not realize the signature and not
translate well the paragraph :>)

> 1) I did not think of (or is think on?) a laser source, I was one step before, I think only of a "coherent" source to match monofrequency simple AC generator analogy.

Let's consider an *ideal* single-frequency laser to be a coherent monofrequency source for the purposes of discussion.

> 2) What would be Rs optical analog?

I don't know enough about lasers to answer that question. In any case, I don't think reflections incident upon a laser encounter whatever Rs that might exist. I think we are going to have to settle for what happens outside of the laser which in important because what happens to photons in free space and other mediums cannot be hidden inside a transmission line. Standing waves of photons cannot stand still in a coaxial transmission line any better than they can stand still in free space.

What some people are missing is that visible light waves and RF waves are exactly the same phenomena, just at a different frequency. The laws of physics governing light waves also govern RF waves. When someone says, "RF waves are different from light waves" or "RF waves can stand still", they are just showing their ignorance. They must also prove that reflected visible light waves in free space contain no energy and can stand still or else they are just blowing smoke.

> 3) Superposition is a medium phenomenon =BFyes?, for example "eter".
> Interference an result of it on a other "thing", for example photographic plate or screen. Are we agree? K

No, in our context, superposition is the merging of two or more EM waves in any medium. If the waves are coherent, constructive/destructive interference can occur. If partial or complete wave cancellation (permanent destructive interference) occurs, then the energy in the waves that existed before cancellation must be redistributed in another direction AND there are only two directions in an RF transmission line.

I believe that Walter Maxwell defines any reversal in direction of reflected energy flow in a transmission line to be a "re-reflection". I prefer to call what happens to a single reflected wave a 1. "re-reflection" and what happens when two waves cancel a 2. "redistribution" of reflected energy.

> What about the third point? I consider it important because light waves are in three dimensional space, ...

Let's compare coax with 0.2 square inches of cross-sectional area to a laser beam with 0.2 square inches of cross-sectional area. For the

```
same power level, the power density, watts/in^2,  will be the same -
therefore the Poynting vectors will be the same. With such a concept
in place, we can talk about a 100w RF source or a 100w laser source.

Sorry, I misspoke here. Instead of "reflection coefficient", I should have said "index of refraction". The two are related but they are not the same parameter.

Please Google "wave particle duality of light".

well, not quite.  they get slower as they move out from the sun.  look
at the trajectories of solar wind and how it winds out in a spiral.
if that was the carrier of light it would severely distort our view of
the sun.  as it is we can easily see the difference between the speed
of light and the speed of shock waves of plasma (longitudinal waves)
in space... the difference is minutes for light to get here up to days
for plasma waves.

Richard, I'm not sure I understand thrust of your theme correctly. Are you accepting my measurement data as proof of my position, or are you including my data as a happy state of ignorance on this topic?

Walt, W2DU

Cecil, you are missing a basic point about physics.
Classical physics is seen as factual. All other theorems are
replacement attempts to explain paradoxies provided by classical
physics. When ever one reads the duality theorem it is exactly that, a
theorem which many say is a myth that is being perpetuated, but even
so they declare the wave as a function purely because of mathematical
reasons that the wave function has the same mathematics that can be
traced back to those  provided by a particle.
Even so, classical physics holds the major spot in physics where all
other theorems are attempts to topple its position as a collection or
laws or facts.
Maxwell's equations  as are equations by Gauss,
Faraday are today considered to be facts that have yet to be
overturned. Tho I call my work a theorem I can just as easily call
them a series of facts which are still accepted to this day. My
findings only uses facts. Classical physics has yet to be dethroned.
The masters were very smart people who were very careful with words
and interpretations of the visibles whereas even today the double
split experiment is torn with missinterpretations in continuation of a
unproven theory
None of the accepted facts that I have used mention the term of waves
and since these laws are part of classical physics I hold to them.
There has not been any theorem that has been expanded to the status of
```

a law such that classical physics has been displaced. I am using only what Einstein failed to locate that which he needed to further his leanings towards the Standard Model and it was only this failure that provided a reason to look for different viewpoints.
If you have reason to displace the legitamacy of Classical Physics as used by me then state them.
What I have used is short and to the point so I am not presenting a hardship to whome I consider as a qualified engineer
My best regards
Art

```

I used one 10 ft. copper clad steel ground rod and three 10 ft. copper pipes. The pipes had 1/4 inch holes drilled randomly throughout the bottom six feet and allowed me to annually pour an epsom salt solution through them to enhance ground conductivity. One copper pipe was set about 6 inches away from the paired copper clad steel -- this enabled the salt solution to salt the region of both. The two sets were about ten feet apart and joined together with heavy copper clad steel wire (Silver soldered). . To one set I attached a number of random length radials running across the yard (along two fence lines) and around the side of the house. They gave me a real good ground as far as I

was concerned. Due to illness I recently sold the house, and extracted the
ground system. Surprisingly there was
little if any degredation of the metal elements -- that was after 27 years
in the ground! Both the copper clad steel
rod and the copper pipes were in good shape. Copper is expensive, but it
lasted a long time and took the
worry about whether I had a good ground away.

To install the copper pipes, I first drove in the copper clad steel rod,
then drew it out of the ground with
a car jack and inserted the copper pipes in the resultant holes.

To make the job easy, I had a young ham use a sledgehammer to drive the
copper clad steel pipe into
the ground and jack it back out -- three times! For the fourth hole I did
not have to extract the rod -- it
was left in place.

I'm no engineer, and never did any ground testing (whatever that involved),
but I was totally satisfied
with the system. Do it once right amd then don't worry about it!

That is obvious. Each star has his own whirl.
```

> look
at the trajectories of solar wind and how it winds out in a spiral.
if that was the carrier of light it would severely distort our view of
the sun.

The math for this was done by Stokes before 1850.

>as it is we can easily see the difference between the speed
of light and the speed of shock waves of plasma (longitudinal waves)
in space... the difference is minutes for light to get here up to days
for plasma waves.

The oldest telephone was made from string and cans. We can use the metal
wire.
In the wire can travel the sound waves and the electric waves. The speeds
are also different.
In plasma the ions are the medium for shock waves and the electrons for the
electric waves.

You know almost everything. But you do not know that the teachers are very
nice people who must every year look for new nice students and next look
after them. So they have no time to observe what the scientists and
engineers are doing. They are using the same "pieces to teach".
They started teaching of Copernican's theory 250 years after publication.
So Stokes' aether will be in schools in XXII century.
Do you agree?
S*

Hi Walt,

You understand my "truly kabuki" suitably enough, which means the others must be lurking in the shadows unable to step up to the bench of their own demonstrable scientific commitment.

Your numbers show evidence of source resistance. Like any real resistance, in a complex mix of reactances and phases, all superposition energies collapse to reveal a net value that is either a caloric break-even, gain, or loss. This real resistance is the experience of EVERY correspondent here.

As for your position, your proposal appears to exhibit source resistance where you deny its reality. This is a longstanding difference we have had and I presume will never be bridged.

If you had never opened the door to the conjugate match, because what you argue with your data as support is properly an image-Z match, then you would be on a firmer foundation, rhetorically.

The Z match more close corresponds to the maximum available power transfer theorem and models of Thevenin/Norton sources. Neither of these sources demand a resistor - this was a high school physics artifact with about as much rigor as Sunday school is to theology.

Terman explicitly offers Th�venin's Theorem on the bottom of page 74 continuing onto page 75. He describes the Z match in the middle of page 76. Your argument is what Terman calls an "image-impedance basis." Note the term "basis," it has been my question to you for years as to what basis you have used. I have never gotten an explicit response.

In the second paragraph of 3-8 we find Terman discuss the conjugate basis of matching for maximum available power delivery. I won't belabor what can be read by the multitudes for themselves.

However, beyond this discussion, Terman offers an APPLICATION where its topology is entirely congruent with the propositions being bandied about here. Please turn to pages 262, 263 footnotes to observe plate resistance and grid-leak resistance being offered - not Zs but Rs.

This last point, yet another distraction, probably brings a collective
sigh of relief as the shadows are emptied with those who throng to
argue the meaning of resistance instead of measuring it at their own
bench.

Truly Kabuki.

Whatever reflects, also absorbs and vice-versa.  The notion that the
interface is a singularity (infinitely thin) cannot be found in
reality.  Arguments that hinge on this non-existent property are made
for the novice to intermediate student.  Those who practice the
science of optics at the bench never observe this metaphor in reality.

>What about the third point? I consider it important because light

Superposition is the collapse of all possible solutions to a real one.
To be real, we must have an observer.  Frequently that is called a
load.  That load may be a transducer (light cell).  Without the
observer, both energies are present - nothing cancels.  What is called
redistribution is a superstitious necessity of trying to visualize the
math.  Redistribution is a strained term that is useful as a placebo,
but nothing moves in the redistribution (an irony or a paradox which
is more useful in entertainment).

Traveling along the road of using optical metaphors is troubling for
those who have never worked at an optic bench.  Cut and paste theory
from eminent authors occludes vision.

>I'm no engineer, and never did any ground testing (whatever that involved),

Hi Irv,

In fact you had the perfect opportunity to do simple but effective test through a classic three electrode measurement.

You perform the test three times by rotation among the three electrodes. You apply a HIGH voltage across the two most distant electrodes, measure that current, and measure the potential difference to the third, middle electrode. You must us a high voltage to overcome local ground currents and any cathodic action. 50 or more volts is enough.

Hi Cecil and Richard (thanks for answer my questions Cecil, and add your technical comments Richard).

I reply (is it OK "reply"?) to Richard first because it is part of my comment to Cecil. Yes, Richard. Tonight I said to me: -the worst term that you could use, Miguel, was "ether"- :>), because "ether" is a hipotetical MATERIAL thing, so, as on other material mediums we usually can literally see interference because interference is manifested on matter, but we need photographic plates, screens, retinas, etc. to manifest electromagnetic interference, "loads" as say Richard, ("observer" it is more sutil and difficult concept, I dare not with "him").
I needed know what represent that in a line discontinuity (in a load seems obvious) to better understand Cecil's examples in web page (http://www.w5dxp.com/energy.htm).
....
Before continue I want to do a comment to know if we agree (more or less). We partially think with words or symbols, words and symbols represent concepts or perceptions, concepts are not "out there", as Einstein said they are: "free creations of human mind". There is not energy out there, there is not velocity out there, that things are in our brains (or consciusness if you prefer). We need consensus to collective think on it, we need "sincrhonize" our minds to colectivelly think the world...
You think in english, I think in spanish, I need translate "your" words to "my" words to understand what you say, I can not say: "whats the hell is a rig!", where are "rigs"! only there are "equipos" boys! :>) For that I need understand what means Cecil with redistribution, I belieive I can understand his idea behind the word, I must make the effort because my own language barrier. Perhaps the consensus word to it may be not "redistribution", but... what Cecil tries explain to me? I try never identify the "map" (words, concepts) with the "territory" (hipotetical real world) because misleading me.
....
Cecil I want to ask you if you are using "photon" term to methaforically refer to "light". I am not qualified at all to address this issue in quantic physics terms I thougth we was fully inmersed in ondulatory theory.

I do not have useful knowledge in laser either. but I can imagine (I believe) the properties of Rs analogy.
I am interested in your optical analogy because analogies often are useful to visualize a new thing knowing old things, it does not matter if we use RF concepts to aproximate optical things or vice versa, analogies are useful crutches (muletas in spanish). Even I agree at our concept that electromagnetic spectrum includes RF waves and ligh waves and they are the same phenomenon, I think that is a result of great insight and efforts of the human mind, it is not so evident. We see light, we sense infrared radiaton, but we can not perceive well RF without instruments (unless we introduce ourselves in a micowave oven or burn with the antenna, of course).
To concentrate light we only need a piece of glass, to do the same on HF RF region we need large wire antenna arrays. Because of this we often need (or employ) very differents models to deal with the "same thing". Probably Maxwell equations solve all of them, but they are difficult ladies to deal :>).
Reconciling optcs models with electric models have its difficulties, but can be productive undoubtedly I believe.

(Richard I do not think wathever reflects also absorbs (ideally at last), It can reflects an transmits but nor absorb, do you agree with it?)

(I do not forget Roy's article, I'm still trying to sort out all the puzzle pieces).

73

Hello Richard,

I must be honest with you, Richard, for over the years I have often been in a quandary after reading some of your posts--I simply don't comprehent what you're saying in them. I often have to turn to look at some one else and ask " wad't he say? wad't he say?" For example, I don't know what a 'kabuki' is.

You say my numbers show evidence of a source resistance. Then you also say "This real resistance is the experience of EVERY correspondent here." On the contrary, my understanding is that Keith Dysart and Owen Duffy don't agree with that. Have I misunderstood their posts? Then you say,"What is more comic is both sides couldn't agree more! Truly Kabuki." Again, what is 'kabuki'? In other words, to both sides agree or disagree? Which is it?

In another paragraph you say, "As for your position, your proposal appears to exhibit source resistance where you deny its reality. This is a longstanding difference we have had and I presume will never be bridged." I totally misunderstand that statement, especially a longstanding difference that I didn't know we had. And although my measurements of source impedance (or resistance) indicate their reality, I have never knowingly denied their reality. I can't understand how you could have reasoned that I denied it.

Now we come to the "basis" for my measurements. You state that my measurements appear to be on the basis of image impedances. According to my editions of both Terman and Everitt, 'image' impedances mean that when the generator is connected to the input terminals of the network the impedances looking in both directions at the output terminals of a network are equal. I understand that this can be true if the impedances are purely resistive, but I can't see how this could be true when the impedances are complex, having reactive components.

If the impedances in both direction contain equal reactances (not opposite), then delivery of maximum available power cannot be delivered. For the maximum power to be delivered the reactances looking in opposite directions MUST also be OPPOSITE, describing a conjugate relationship, not an image relationship.

Unfortunately, my editions of Terman must be different from yours, because I find no mention of plate resistance (Rp) or Rs. Rp is a factor in determining the value of RL that appears at the input of a pi-network in an RF power amp, but has no relevancy downstream of the network input, and certainly has no relevance to the formation of a conjugate match at the output of the network.

So Richard, let me get this straight--are you agreeing with my position or disagreeing?

Kabuki?

Walt

Representing, representation, like the term redistribution, are all
crutches for intellect. If you get stuck on one, you are forever
behind. If it works - fine. When the crutch breaks, you have to be
able to walk away without feeling cheated. (Amusing, being able to
walk away means you never needed the crutch in the first place.)

Redistribute is an action verb. Nothing happens until you measure it (you need a load). This speaks to your Ether (or Aether or �ther) being a medium, but there is no evidence of Ether existing. So for action, it is in the loading - nothing else happens (has action) without a load.

The "concept" of redistribution collapses to zero if you do not take a measure, but it exists if you do? Logically, the causal relationship is with the observation, not with the energy. The load reveals a concept that does not exist without it.

What you wonder about and call a map, or territory, is a forest of loads that give a population of varied responses that are a product of phase differences. Mathematical "representations" of this are called surface maps (your term of map is appropriate) or contour maps. Within these types of representation, you can see patterns. However, the patterns are those revealed by a multitude of loads. Take away the loads and you would see nothing.

>(Richard I do not think wathever reflects also absorbs (ideally at
>last), It can reflects an transmits but nor absorb, do you agree with
>it?)

No. I have measured light at the bench, and I have studied its applications at many scales down to subwavelength dimensions. All materials absorb light without qualification. All materials reflect light without qualification. All materials transmit light without qualification.

You may be tempted to tightly constrain what you call light to force an artificial solution. Do not do it, because that serves no useful purpose.

Consider the sun, light (a photon) from its center has to penetrate its bulk before we see it. It takes something like 10,000 years for that light to reach the surface. Any material you think of here on our mud ball planet is inconsequential in comparison.

Using an optical analogy for RF is very dangerous if you cannot measure it at the bench. Why try to understand two unknowns together?

The greatest danger of an optical analogy is in your perception (I choose that word with care) that IF you are able to "see" it, THEN that means that you "understand" it. Sight is an illusion (another word chosen with care) that is most often clouded by the mind. This topic fills books from both academic and popular writers.

In simple terms, there are optical events that you are certain you can see, but that you cannot measure or show anyone else. There are optical events you and others can measure, but you cannot see.

A simple (but complex one to build) example is the conjugate mirror.
It reflects light, but when you look into it, all you see is black. If
you have no experience at the bench, then what I write is a puzzle.
Although I have described why this happens, I doubt anyone remembers
or knows the answer to this contradiction.

If you want a hint, it relates ENTIRELY to your trying to tie together
RF, reflection, and other transmission/transmitter topics. Look at
the ongoing discussion on source resistance, and note the same word
conjugate's appearance in that commentary.

classical physics has been well dethroned by both relativity at the high velocity end and quantum mechanics at the small side of the scale. classical physics does good at 'every day' speeds and for macroscopic things... the types of things that newton and his contemporaries would have been able to experiment with. they could not have known or measured things at very high energies as seen at relativistic speeds, nor could they have measured things at subatomic levels where the 'classical' laws break down.

Hi Walt,

Your confusion is well founded. :-)

Kabuki - Japanese theatre with very elaborate costumes and highly mannered acting. It is presented in day long plays that many in the audience feel perfectly at ease with watching, talking to a neighbor, eating a meal during the performance or taking a break and coming back to after an hour or so.

>You say my numbers show evidence of a source resistance. Then you also

>is 'kabuki'? In other words, to both sides agree or disagree? Which is
>it?

Both. However, as to why? They themselves are notably absent from this discussion. I mark this as a lack of commitment at the bench to obtain contrary evidence. Perhaps it is casual indifference carefully woven into passionate and emphatic negations. Such bipolar swings is what I term as truly Kabuki.

>In another paragraph you say, "As for your position, your proposal
>appears to exhibit source resistance where you deny its reality. This
>is a longstanding difference we have had and I presume will never be
>bridged." I totally misunderstand that statement, especially a

>>
>>>Rp is NOT the source resistance.

Note your emphasis in the original. It conforms to half the other writers half the time (who can tell with all their mannered elaboration?).

If you can allow that Rp is real resistance, all fine and well. If it takes more than three sentences to state it is not, then that is truly Kabuki. Three sentences may not completely give you enough freedom of expression, but if I see a fire hose response - that is just too much material to justify parsing for a clear answer.

>Now we come to the "basis" for my measurements. You state that my

>be true when the impedances are complex, having reactive components.

Well, you have the material at hand. Terman offers succinct meaning. A position is usually in one place. That place is as Terman and NBS writer Stephen Adam (strictly) terms it as "basis." And I asked what basis you use. Please consult the strict usages of the literal word basis (and not the informal understanding of "how") to avoid mixing them. Your pleas are often couched with conjugate basis and you attempt to prove them with image-Z basis. They should not be intermingled.

>If the impedances in both direction contain equal reactances (not
>opposite), then delivery of maximum available power cannot be
>delivered. For the maximum power to be delivered the reactances
>looking in opposite directions MUST also be OPPOSITE, describing a
>conjugate relationship, not an image relationship.
>
>Unfortunately, my editions of Terman must be different from yours,

You do not have "Electronic and Radio Engineering?"

>So Richard, let me get this straight--are you agreeing with my
>position or disagreeing?

I take no position beyond your data clearly exhibiting the nature of what Terman describes in pages I have referenced. My professional experience has been invested with measuring real resistance to NBS precision and accuracy - this includes plate and collector resistances (albeit at vastly less resolution than standard resistors and such).

Energy creates heat in real resistors. The combination of phases and energies in a resistance still gives rise to heat, if by different degrees that follow phase relationships of all perceived sources. Heat can increase through soaking (a steady elevated current) or through breakdown (the quick flash of an intense voltage arc). These two are very common (even if only on rare occasions) experiences of EVERY correspodent with their own equipment. It is exceptional to deny this. We have exceptional threads.

Your data does not contradict any of my points - the question is: does your position contradict Terman's discussion and my experience? I have trouble with your mixed basis discussion that clouds my ability to resolve where you stand. Other writers seem to go both ways without any data of their own measurements to inform me about their judgment having authority. Yours is the only data (aside from my own offered earlier in separate discussion) on the table - and it suits me fine.

73's

K1RRR@ARRL posting response by Art Unwin

Are you saying that the laws of Newton, Faraday, Maxwell and Gauss is
now defunct? What should I have used in their place if they were no
good in the areas that I worked with?
Why on earth did NEC work around the equations
of Maxwell when they had been toppled? I used Newton,Faraday,Maxwell
and Gauss's laws only.
Who and what has replaced them in the areas where I mistakenly used
them. Did Ohms laws
survive this onslaught and who got the award from Oslo? I would like
to have another stab at my work
using the data that has replaced them, so I could do with some
guidance from you so my work is not wasted again. Do you know what the
replacement antenna computer programs will be based upon and are any
presently available on the market?
Thanks for the update. Why not share what you have with QST so your
fellow hams may benefit
from the up to dated textbooks now supplied to the new generation in
Universities. I heard that Texas
is redoing all the school textbooks but I didn't realize that
education had taken such a radical change. And of course as science is
changed in Texas so goes the whole Country. On another thought, will
degrees obtained before this update be grandfathered in?
My very best regards
Art Unwin

Art and S are running remarkably parallel today. Funny how people like
that can sync up once in a while.

>
> 73's
> Richard Clark, KB7QHC

Richard, I'm still trying to assimilate all the info you presented in you post above. So please allow me to skate around a bit.

First, concerning plate resistance, Rp. This may be where we don't understand each other. My position on Rp is that it is a non-dissipative resistance, and can be measured by noting the change in Ip with a change in ep with grid voltage held constant. The result of the effect of Rp is thus one of inverse feedback when the Ip is varying with respect to a change in grid voltage that causes a change in Ip that is inversely related to the change in ep appearing across the plate load resistance with the plate source voltage held constant. Rp thus is not relevant to the source resistance of an RF power amplifier other than its effect on RL looking upstream of the input to the pi-network. When I speak of the source resistance (or impedance) of the RF power amp I'm referring to the resistance (or impedance) appearing at the output terminals of the network, which has nothing to do with Rp. If you're considering Rp as the source resistance that's probably the reason for our disagreement, and if you do consider Rp as the source resistance I believe you're wrong.

And concerning the basis for the impedance matching, I don't consider that I'm comingling image impedance with conjugate impedance. I simply can't construe Terman's definition of 'image' impedance as relating to the procedure I used in measuring the source impedance appearing at the output of the network. This is because Terman says the image impedance at the output terminals of the network is the same looking in both directions. This condition cannot occur when the reactance component in the load is the opposite to that looking rearward into the network, a condition required to satisfy the Maximum Power Transfer Theorem with respect to delivering all the available power.

However, I will say this, I appreciate your statement that my data suits you fine.

Walt

Hi Walt,

Thank you for the restrained answer.  Yes, we do not agree here.

To the matter of the conjugate basis.  Terman quite distinctly gives
us a real R that remains after the cancellation of reactances.  As a
hallmark of first principles, it is very clear and concise.  The
source R must match the load R for the source to deliver the maximum
available power.  By the same hallmark, this too is very explicit.
Terman calls this R (the remnant of conjugation) in the source: "the
resistance component of the generator impedance."

For you and others to say what the source is "not," that is not a
solution for what the source "is."  This is what I speak of when you
ask if your critics agree or disagree.  You stand with your critics
against the testimony of your data that stands with Terman.

The plate resistance can be described physically to suit any objection
that I have so far heard from the community.  It suits very few who
embrace thought experiments that have never warmed a bench nor
flickered a measurement instrument.  The collapse of rhetoric has
exposed the vacuum of counter argument.

>However, I will say this, I appreciate your statement that my data
>suits you fine.

Walt, your methods are first methods.  Your care for propriety exceeds
all bold statements that carelessly condemn you.  Your achievements
give you the status of not having to endure taunts and endless
bickering.  Your steadfast self examination and willingness to sit at
the bench is the rock of faith in what Hams aspire for in engineering.
As for your humanity, I find you a proud father and loving husband.  I
think of you in no other terms, even when my prose is dense or obtuse,
and my engineering demands are harsh and pointed.

If my allusions to Kabuki are obscure, it is through my upbringing
living in Japan as a tyke.  If I might balance that obscure reference
for one that is more to my tone here, I call you Sensei - a master of
learning and teaching.

Hi Richard.

Really brilliant and good arguments, it is a pleasure for me to read
them. In certain dialog level I can agree with almost all of it (I
said I am interested in knowledge theory or science philosophy) but,

you know, they are philosophical and controversial topics. Reality, duality, consciousness, observer...
In technics we are (or use) a much more naive vison of world and It works!, there is not strange Schr=F6dinger cats in ham radio! (or in radio technics) :>)

Models Richard, all are models, mathematical models, physical models, naive models, "Ideas", representations of "reality" in our minds. We, humans, walk with our crutches -always- =3D> simple crutches, elaborated crutches, little crutches, BIG crutches... :>)
All of my physics and electronics books have "representations", thousands of them, why not? they work...! -except when don't work :>(- Well...when not work =3D> chao with electron "little balls", chao with clasical electrodynamics, chao with Newton's laws, chao with Reality!, It is good for me... very exciting!

I understand what you say Richard but also I think that you seems (to me) adscribe to a sort of, "right model" or "true model", I'm not, I am a little exceptical about "truths" o "rigth sciences", for that reason I like listen as carefully as I can, others ideas. Listen, this not a criticism to you, remember I said "In certain level of dialog I can agree..."

The bench... all of my life spent on the bench. The bench it is a good friend, -probably an essential friend- but tends to be a fa little "gross" friend. We need also a rational friend (and -why not- an intuitive friend) to make a bingo. With "rational" friend we have, mathematics, calculus, idealized models,:real world is: this tree, that tree, it is not easy (for not tell impossible) to understand a world of individual trees. Rational friend invents the "ideal tree" (certainly not a "bench tree") and works...! we can operate very well with ideal trees!, we can put them into simbolic equations, inside computer memories, good thing (for me) ideal things, total reflection, full transparent thinghs, cuasi-infinitely thin things.

Yes, analogies are dangerous, I know, women too... I dare to risk :>D

> It reflects light, but when you look into it, all you see is black.

Very interesting thing, I like to see one (better if I can understand it)

Richard, I feel that I must to return to Ham radio world and try to see if it is possible compatibilize my old Terman model with yours. This dialog does not bother me at all, as I said It is a pleasure, but without wanting, I am going out off topic :>) I truly enjoyed your comments.

73

Miguel

PS: Certainly I did not postulate the existence of an ether, here we usually call it figuratively, like an old friend, as a kind of "Santa Claus".

You know almost all but only almost.

There are many aethers. One of them was Lorentz' aether in form of
motionless solid body. No such without any doubts. So it is obvious that it
is debunked.

You know that the Sun rotate together with the plasma and the dust. The
plasma and the dust is the Stokes' aether.
In that time another scientist Ludvig Lorenz was sure that in space is
enough matter to propagate the waves.
Both of them did not know that the electron exist.

Teachers could not stay up to date because the all is the top secret.

I am in Stokes' time. Art citates the all super modern theories. Where you
see the synchronisation?

>it)

You can't see it! That is the point. It is also by definition. To understand it, you have to understand the conjugate match. Have you been following that story with Walt and myself?

Like I said, trying to learn two things at the same time, when you cannot understand either of them singly, is foolish. Metaphors (RF as photon theory) often fail at the wrong time without being noticed.

A 60 Hz Power Generation Plant operates at high efficiency, not at the
maximum power transfer point. If they were 50% efficient, they would
go out of business. (That's what Edison expected.) Why is maximum
power transfer desirable in ham transmitters? Is such a design the
highest power/cost ratio? Is it possible to build an output amp with a
10 ohm source impedance designed to be 80% efficient? 1 ohm source
impedance designed to be 98% efficient? Is co$t the driving parameter?

That will work if that's what you want to do.  The radio's ferrite
antenna replaces the 2 turn pickup loop.  If you want to be able to do
both, include the pickup loop anyway.

Good luck!

tom

On May 25, 5:29=A0am, Keith Dysart <keith.dys...@gmail.com> wrote:

> It does not seem possible for a system to be non-linear at one end and
> turn in to a linear system at some other point.

Well, consider the following two systems. Z01 is 50 ohms and Z02 is 300 ohms. The two systems are identical except for the circuits hidden inside the two identical source black boxes. Both sources are supplying a 100v sine wave to the system.

Source1----Z01----+----1/4WL Z02----1800 ohm

Source2----Z01----+----1/4WL Z02----1800 ohm

Every passive voltage, current, power, and impedance measurement is identical in both systems. As far as we can passively measure, both systems are identical and linear. The only thing we don't know is what is inside the two source boxes..

Inside the Source1 box is a linear ideal 50 ohm Thevenin equivalent source delivering an ideal 100v sine wave. Inside the Source2 box is a non-linear class-C amplifier filtered to provide an ideal 100v sine wave.

Without changing the system conditions, can one make a passive measurement to determine which system is conjugately matched and which one is not conjugately matched? If one cannot tell the difference, are

they both conjugately matched, or both not conjugately matched, or
what?

Here's my take. A 50 ohm Z0-match exists in both systems and all
conditions are identical on the load side of that Z0-match. In
particular, at any point in the system on the load side of the Z0-
match, the impedance looking in one direction is the conjugate of the
impedance looking in the other direction. That is a characteristic of
a conjugate match. So are both systems conjugately matched between the
Z0-match and the load? If it walks and quacks like a duck ...

On May 25, 2:56=A0am, Roy Lewallen <w...@eznec.com> wrote:

> The chart and discussion in the "Forward and reverse power" section show
> that the concept of "reflected power" being absorbed in or dissipated by
> the source is incorrect.

I'm sorry, Roy, but that is a very misleading statement. There are THREE things that can possibly happen to the reflected energy.

1. It can indeed, be absorbed/dissipated by the source but it certainly doesn't have to be. The conditions governing absorption, reflection, and redistribution of EM wave energy are well understood in the field of optics. RF gurus seem to be myopic about interference effects.

2. It can obey the laws of the reflection model for EM waves, e.g. if the source impedance is different from the Z0 of the transmission

line, some reflected energy will be re-reflected. (I know that doesn't apply to your "food for thought" examples because the source resistor is equal to the Z0 of the feedline.)

3. The interference phenomenon that you completely ignored in your discussion, presumably through ignorance. This third possibility for the reflected energy redistribution is associated with constructive and destructive interference. It is the same phenomenon that is in operation with the 1/4WL coating on non-reflective glass. Here's a quote from a Florida State University web page with capitals added by me for emphasis:

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... ALL OF THE PHOTON ENERGY present in these waves must somehow be recovered or REDISTRIBUTED IN A NEW DIRECTION, according to the law of energy conservation ... Instead, upon meeting, the photons are REDISTRIBUTED TO REGIONS THAT PERMIT CONSTRUCTIVE INTERFERENCE, so the effect should be considered as a REDISTRIBUTION OF light (and RF) waves and PHOTON ENERGY rather than the spontaneous construction or destruction of light."

This is the concept that you have been missing for eight years. "Redistribution of energy" in a transmission line is simply a reversal of energy flow. Each of your examples have different magnitudes of interference (depending on the phasing between the forward energy and the reflected energy). The phasing is a variable for all of your examples. Why did you completely ignore the interference? Why would you expect a CONSTANT magnitude of reflected energy to be dissipated in examples with VARIABLE phasing and VARIABLE levels of interference??? Here are the possibilities:

1. No Interference at the source resistor - this happens when the forward wave is 90 degrees out of phase with the reflected wave at the source resistor. In this case, the reflected energy is indeed dissipated in the source resistor. I have written a short article on the no interference case at:

http://www.w5dxp.com/nointfr.htm

2. Constructive Interference at the source resistor - This happens when the phase angle between the forward wave and reflected wave is less than 90 degrees at the source resistor. The voltage across the source resistor increases and therefore more power is dissipated in the source resistor. In fact, for total constructive interference, all of the forward power and all of the reflected power is dissipated in the source resistor. This happens when the SWR is infinite and the reflected wave arrives at the source resistor in phase with the forward wave from the source.

3. Destructive interference at the source resistor - This happens when the angle between the forward wave and reflected wave is between 90+ degrees and 180 degrees. In this case, reflected energy is redistributed back toward the load and less is dissipated in the source resistor. In fact, for total destructive interference, zero reflected power is dissipated in the source resistor and all of the reflected energy is redistributed back toward the load. This happens when the SWR is infinite and the reflected wave arrives at the source resistor 180 degrees out of phase with the forward wave from the source.

I explained all of this in my "WorldRadio" article way back in 2005. Presumably, you have never read it. In order to understand the role that interference plays during the superposition of EM waves, you might want to read it and take a look at the references. The question of where reflected energy goes was answered long ago by optical physicists. Too bad that RF gurus remain so ignorant of that knowledge. Here's that five year old "WorldRadio" article.

http://www.w5dxp.com/energy.htm

You obviously know how to add voltage phasors but you are obviously ignorant as to what happens to the ExH power in each of those waves. In any optics reference book, you will find the following irradiance equation. Since irradiance uses the same units as the Poynting vector, I have changed I (irradiance) to P (power density) in the irradiance equation. I first saw this equation in Dr. Best's QEX article[1].

Ptot =3D P1 + P2 + 2*SQRT(P1*P2)cos(theta)

When any two EM waves are superposed, whether light waves or RF waves, this is what happens to the component powers. The phase angle, theta, is the relative phase angle between the two electric fields before superposition. The last term in the equation is called the "interference term" and it is easy to see how it modifies the total power in the wave after superposition. Energy must be conserved. If destructive interference occurs between two waves in a transmission line, constructive interference must occur in the opposite direction - and vice versa.

By completely ignoring the destructive and constructive interference occurring in your "food for thought" examples, you have ignored the accepted laws of physics (available in any physics optics reference) and arrived at completely false conclusions. Roy, every one of your examples can be explained simply by using the above equation from the field of EM wave optics. Differing types/levels of interference explains every one of your examples perfectly.

Miguel, let's switch your example over to an easier to understand example. Assume an ideal signal generator equipped with a resistive circulator load. Let's call such a device an SGCR, a Signal Generator equipped with a Circulator and a Resistor. Assume that 100% of the reflected energy is dissipated in the circulator load resistor (none re-reflected) and none of the reflected energy reaches the source. So here is the block diagram.

SGCR--------feedline--------load

That model should be easier to discuss than the pad attenuator model.
What do you think?

Hi Miguel,

Your translation is fine.

However, I have no idea what the pad design looks like, nor do I know the component values. I have calibrated thousands of standard pads at frequencies up to the 12 GHz. They came in either a Pi design, or a T design. Their intended use is in system isolation. That is, they isolate the source from the load OR isolate the load from the source OR isolate both. For certain component values, you can replace the "OR" with "AND."

You would isolate the source to keep its frequency and power constant. You would isolate the load to keep line SWR flat. For this line application, it is assumed you are calibrating either a load equal or nearly equal to Zc, or you are measuring RF power. These are the purpose of pads (they also serve the same function in audio circuits). Measuring power in the presence of SWR other than 1:1 requires sophisticated math that is rarely discussed here. Most discussion usually accepts the presumptions of special cases (which are often sufficient) and employ less rigorous formulas (which serve well within the unstated presumptions).

In conventional Kirchoff analysis, the resistor that bridges the transmission line opening becomes the source (that is Vs and Rs). Pad design usually makes that one resistor for the Pi pad, or two resistors for the T pad. If you are working in accurate and precise measurement, you then account for the input (source) resistance in parallel/series combinations. This second computation is the numeric analysis of isolation. The higher the ratios of these pad resistors, the higher the isolation.

It doesn't normally serve any use to have the pad apparent resistance (what I called Rs above) different from Zc or from Zload, but as this component is a sacrificial one, the designer may choose to put it to use to achieve a desired goal. Pad performance suffers with heat due to energy combinations that come from multiple/single sources.

The counter argument, as I understand it, is that the tank circuit isolates the linear from the non-linear, and that the tank also performs the action of transformation. Thus the proposal is an analysis of their combination (I had to struggle to avoid superposition).

Thus, the non-linear Tube (because, I presume, the circuit is in Class C operation) exhibits a higher efficiency than would be found in a resistance matched system. What I call the resistance matched system is the unfortunate appeal to a source "resistance" equaling the load "resistance." Thevenin/Norton do not mandate resistors, rather impedances.

What I understand, comes from lengthy emails with multiple contributors in years past: Walt and Richard being two of them. My saved mail only goes back nine years, so the other two contributors' names are lost to me right now.

Of course what I "understand" may be wholly misrepresented by my exposition here. So be it. The source authorities can correct my deviations.

Yes, that is quite correct Cecil, and nothing that I have written says or implies or is intended to mean otherwise.

However, your own words in another post
(news://news.bigpond.com:119/c8b7540a-42d1-4ed8-a203-503fc6f754ea@w3g2000vbd.googlegroups.com)

"A 60 Hz Power Generation Plant operates at high efficiency, not at the maximum power transfer point. If they were 50% efficient, they would go out of business."

demonstrates that whilst you apparently can quote from text books, you do not necessarily understand what you are quoting. You do talk nonsense sometimes!

Owen

Owen, my reference supported what you said! Why are you trying to pick
an argument? As my mother would have said, "You would argue with a
fence post".

by definition, an IQ of 100 *is* the median, and the standard deviation
is 15. IQ is a normalized measurement.  (it hasn't been 100*mental
age/chronological age for decades.. )

And there's a radio connection here.. Lewis Terman, who invented the
Stanford-Binet IQ scale was the father of Frederick Terman, of EE fame..
both were at Stanford.  And Bracewell (another EE) held the Lewis Terman
professorship

Hi there,
I have had some experience with BCB boosters and found that it works
best with a long wire coupled to a loop that is grounded. The radio I
was using had a built in antenna wound inside the case and the untuned
loop coupled very nicely to the radio. With a ferrite rod inside the
radio it might not work so well.
Just an idea for you to play with.
Bill Baka

```

Hello Keith,

Thank you for your response. I=92m starting my answer to your statements by first quoting from one of your posts:

=93Try as I might, I have not been able to derive a mechanism to explain the observations in Reflections. But the explanations offered in Reflections require large chunks of linear circuit theory to be discarded, so this does not seem to be an appropriate path.=94

That you have been unable to derive a mechanism that explains the action in an RF power amplifier is evidence that you do not understand it. So let=92s examine the action that follows an appropriate path that does not require any linear circuitry to be discarded. Further evidence that you do not understand it is that you used a bench power supply to describe the action, which you state has an infinite source resistance when the load exceeds 50 ohm, and zero source resistance when the load is less than 50 ohms. Unfortunately, this power supply in no way resembles an RF power amplifier, either in components or action.

We=92ll begin by stipulating that the =91filter=92 is a pi-network tank circuit, having a tuning capacitor at the input and a loading-adjustment capacitor at the output. We=92ll also stipulate that the plate voltage and the grid bias are set to provide the desired conditions at the input of the tank circuit, which means that the desired grid voltage is that which results in the desired conduction time for the applied plate voltage. The result provides a dynamic resistance RL, which is determined by the average plate voltage VPavg and the average plate current IPavg appearing at the terminals leading to the input of the tank circuit. In other words, RL =3D VPavg/IPavg. To permit delivery of all available power to be delivered by the dynamic resistance RL, we want the input impedance appearing at the input of the tank circuit to be equal to RL.

We=92ll now go to the output of the tank circuit. We=92ll assume the load to be the input of a transmission line on which there are reflections. The result is that the input to the line contains a real component R and a reactance jX. The output terminals of the tank circuit are the two terminals of the output-loading capacitor. When the line is connected to the output terminals of the tank circuit the reactance appearing at the line input is reflected into the tank circuit. This reactance is then cancelled by the tuning capacitor at the input of the tank circuit, resulting in a resonant tank circuit. We now need to adjust the output-loading capacitor to apply the correct voltage across the input of the transmission line so that the real component R appearing at the line input is reflected into the tank circuit such that the resistance RL appears at the input of the tank circuit, thus allowing all the available power to enter the tank circuit. In other words, adjusting the loading capacitor to deliver all the available power into the line also makes the output resistance of the tank circuit equal to the real component R appearing at the line input. With any other value of output resistance of the source, all the available power would not be delivered to the line. A corollary to that condition follows from the Maximum Power Transfer Theorem that for a given output resistance of the source (the tank circuit), if the load resistance is either increased for decreased from the value of the source resistance, the delivery of power will decrease. This condition also accurately describes the condition for the conjugate match.

Keep in mind that the input impedance of the line is complex, or reactive, but the reactance of the correctly-adjusted tuning capacitor has introduced the correct amount of the opposite reactance to cancel the reactance appearing at the line input. Thus the line input impedance is R + jX and the output impedance of the source is R =96 jX, providing the conjugate match.

You stated in one of your posts that the phase of the reflected wave in relation to that of the source wave results in a non-linear condition. This is totally untrue. The tuning action of the input capacitor in the tank circuit that cancels the line reactance caused by the reflection on the line in no way introduces any non-linearity in the circuit, and the condition in the vicinity of the output of the tank circuit is totally linear. Thus, circuit theorems that require linearity to be valid are completely valid when used with the RF power amplifier as described above. This applies to all RF power amplifiers, Class A, AB, B and C.

I hope my comments above assist in understanding the action that occurs in RF power amplifiers.

Walt Maxwell, W@DU

I didn't know that. I may not be broadcast here in California or it is
just lost in the hundred channels or so on cable.
Cheers,
Bill Baka

Sort of.
Start with two parents who are above 140 and encourage them to have kids
and educate them starting at day one. It would obviously offend the
Vatican, but religious beliefs are fantasy anyway. Just discourage
people with low IQ's so they won't breed like rabbits. It could/would
work if people weren't so hung up about their right to have children.
That show on TV, 19 and counting makes me sick. People like that are a
major cause of de-evolution.

Yup.
I know about it but I don't think I could top that after 61 years.
My diet had way too much beer from 21 to 54, when I finally quit that
habit. Had my parents encouraged me instead of kicking me out of the
house to play with 'normal' kids I might have made it, but I don't think
I am that high on the scale. Somewhere around 160'ish is my best guess
but I am somewhat apathetic about it right now.
Cheers,
Bill Baka

Hi Bill,

It is on at least twice during the weekend on NPR (I don't think anyone else, commercial radio, has ever carried A Prairie Home Companion). Robert Altman made it into a movie 4 years ago.

NPR is usually found in the public service (think campus stations) end of the FM band.

Wow, I'm in awe of the great levels of genius represented here on this humble forum! And if boys ever outgrew the "mine's bigger than yours" compulsion, we never would have known -- or even suspected! Thanks so much for sharing your IQs, whether known, suspected, or just claimed, with us. You geniuses will be expected to provide brilliant insights into those sticky problems which have eluded not only us, but also the relatively pedestrian intellects of the likes of Termin, Maxwell, and Kraus. Art has already shown the way and set the bar. Go for it!

Roy Lewallen, W7EL

I apologize for misspelling Dr Terman's name. Poor spelling is just one
of the handicaps of having such a low IQ. Carelessness is another. It's
a tough life.

Roy's notes lead you into thinking about instantaneous power, and the behaviour over a complete AC power cycle. Thinking that through, and the implication about the power/time graphs at various points on the transmission line gives insight into average energy flow, and energy exchange between line sections, line and load and line and source, and the physical bounds of exchange of stored energy during a cycle.

The Telegraphers Equation that I mentioned earlier captures the behaviour of the line, and basic AC circuit theory, Joule's law etc takes you the rest of the way.

Sure, working these things through takes time... and there isn't much afforded in today's world of instant gratification where appealing explanations are more accepted, irrespective of whether they are correct.

Miguel, invest in yourself and your knowledge, don't accept explanations
because of a vote count, accept them because they reconcile with things
that you truly know as facts (which sometimes means challenging what you
think you know).

Owen

Virtually every public broadcasting station carries it, at least in
southern California.

Thanks Roy.  About time someone made a comment.  I have been near
projectile you know what for a while.  I can claim a lot too.  Meaningless.

On the other hand you have produced verifiable product.

tom

Methinks you have so constrained the experiment as to make it
unsolvable.
But let us test that.

Consider a Source3, much like Source1: linear, ideal, but 100 ohms
output impedance. It is connected to the same load you specify for
Source1 and Source2 and adjusted to drive 100 volts in to the 50
ohm Z01 line.

You are presented with the circuits using Source1 and Source3.

We know that Source1 and Source3 can not both be conjugately
matched.

"Without changing the system conditions, can one make a passive
measurement to determine which system is conjugately matched and which
one is not conjugately matched? If one cannot tell the difference, are
they both conjugately matched, or both not conjugately matched, or
what?"

Some people just don't like the show. Even those of us that live nearly next door to the clod that makes the it. No offense, but he is not nice a nice guy and is quite offensive to the local population.

Not kidding.

Measuring power in the presence of SWR other than 1:1 requires sophisticated math that is rarely discussed here. =A0Most discussion usually accepts the presumptions of special cases (which are often sufficient) and employ less rigorous formulas (which serve well within the unstated presumptions).
>
> In conventional Kirchoff analysis, the resistor that bridges the transmission line opening becomes the source (that is Vs and Rs). =A0Pad design usually makes that one resistor for the Pi pad, or two resistors for the T pad. =A0If you are working in accurate and precise measurement, you then account for the input (source) resistance in parallel/series combinations. =A0This second computation is the numeric analysis of isolation. =A0The higher the ratios of these pad resistors, the higher the isolation.
>
> It doesn't normally serve any use to have the pad apparent resistance (what I called Rs above) different from Zc or from Zload, but as this component is a sacrificial one, the designer may choose to put it to use to achieve a desired goal. =A0Pad performance suffers with heat due to energy combinations that come from multiple/single sources.

Dear friends

Sincerely it was not my desire to vivify old polemics but to tell the truth, eight years it is a lot of time for not having arrived to a consent!; hey boys this is science non religion! We must have a way of leaving the well! :>)

Is not possible you are using different models to describe an only one phenomenon?, as looking at the same cat from their muzzle or from his tail believing each one his cat is the true or real "cat" :>)

I finished reading Cecil's article (http://www.w5dxp.com/nointfr.htm) and I took of his example that of the 12,5 ohm load. I took a Smith's chart and obtained the line input impedance, then I applied basic circuits theory and I obtained the same value of power dissipated in Rs -exactly-
As I see, if we use a simple electric model of generators and impedances to solve the problem (maybe like Owen suggests), we can explain the dissipation in Rs without appealing to any reflected power returning into the generator because the interference phenomenon that Cecil describes takes place to form the impedance that generator see.
Or alternatingly the dissipation can be described by means of the equations that Cecil shows in its page. In such case we should consider both powers (direct and reflected) operating simultaneously on generator resistance. Same cat, different points of view... :>)

Perhaps my vision is naive but this situation reminds me an example of

Sears and Semansky book "University physics" (third edition) where he explains that energy can be thought as not transported by charges in movement, but for the electromagnetic field associated to them. Last is a little hard to see -Poynting vector et al- :>) but it is applicable.

Always has been a pleasure for me to read you. I have learneing very much from your enthusiastic discussions. You made me think of things that I never thought without your help. Thank you.

Miguel Ghezzi . LU6ETJ

PS: Meanwhile I take the Owen advice and I am still studying!

Hi Miguel,

You got on this train rather late if all you see is eight years of it.
The circular references have entertainment value - so did vaudeville.

I do admit reading way too much, but I enjoy the professional Magazines
I get in the mail. My reading habits go far beyond just electronics and
compute so I read Military and aerospace, NASA tech briefs, information
week, EDN, Electronics design, and many more. I can at least push my
brain as hard as possible.
BTW, does anyone here know a good grammar checking program.
There are some good windows 7 products but my scanner will not let me
use it in Linux land since h.P. has flat out told me my 4 year old
scanner is now obsolete and they are making new scanners, won't even
attempt to fix the driver mode since H.P. never made any drivers for Linux.
Come summer, if it ever gets here, I will be busy on my 100+ mile
bicycle rides. These take from sunup to sun down, but burn huge amount
of calories climbing endless hills.
Return to school? I might take classes at the local junior college and
collect about three or four subjects and try to get 4 or 5 Associate
degrees. I won't be able to that and actually finish with requirements
that are needed (forced down my throat) So that would be a logical start
for me. Cal state in Sacramento is the next college for the next four
years, but I can challenge some of them.
It is an idea but for the summer I am going into physical fitness and
not computer mode. It may be a little 'old' at my age but I can do the
school work just as easily as ever.
Cheers,
Bill Baka

No excuse, just too far down on the income to actually join one.
My brain is in no position to pay for a membership and and I would not
want to take an IQ test after a night of no sleep. If I qualify for Giga
society I would be amazed. I might just luck out and qualify, but who
knows? I am not intentionally doing anything to average people but some
times I over-estimate people's ability to understand.
Bill Baka

I'm not into the bragging mode and never had to be. Of course I put down
some fellow engineers at one job. All I know is that I can take a look
at almost anything and make it better.
Bill Baka

Some of the people I knew who were the most gifted have led the most wasted lives. Can you imagine having an IQ in the 140s and the focus of your life is antennas. What a waste.

Jimmie

>
> That you have been unable to derive a mechanism that explains the action in an RF power amplifier is evidence that you do not understand it. So let=92s examine the action that follows an appropriate path that does not require any linear circuitry to be discarded. Further evidence that you do not understand it is that you used a bench power supply to describe the action, which you state has an infinite source resistance when the load exceeds 50 ohm, and zero source resistance when the load is less than 50 ohms. Unfortunately, this power supply in no way resembles an RF power amplifier, either in components or action.

=93No way=94 is a bit strong. The RF PA is constructed from a constant voltage source (the power supply) and a constant current controller (the tube), both aspects present in the bench supply example previously offered. A tube is often modelled as an ideal variable constant current source but unlike an ideal source, which can produce whatever voltage is needed to drive the current, the current produced by the tube is limited by the power supply voltage. Thus, assertions of linear behaviour need to be tempered by ensuring that such voltage limits are not exceeded.

> We=92ll begin by stipulating that the =91filter=92 is a pi-network tank circuit, having a tuning capacitor at the input and a loading-adjustment capacitor at the output. We=92ll also stipulate that the plate voltage and the grid bias are set to provide the desired conditions at the input of the tank circuit, which means that the desired grid voltage is that which results in the desired conduction time for the applied plate voltage. The result provides a dynamic resistance RL, which is determined by the average plate voltage VPavg and the average plate current IPavg appearing at the terminals leading to the input of the tank circuit. In other words, RL =3D VPavg/IPavg. To permit delivery of all available power to be delivered by the dynamic resistance RL, we want the input impedance appearing at the input of the tank circuit to be equal to RL.

Most references use Vpeak and Ipeak, though they are usually related to average values with constants of proportionality so the computed RL will be the same. None-the-less, I prefer peak values since it ties better to the choices made in the design.

The power that can be controlled by a control device (be it a switch, tube or transistor) is related to device limitations. So, for example, the maximum power that can be controlled by a 250V 1A switch is 250W. This occurs with a supply voltage of 250V and a load of 250 ohms. Increasing the supply voltage exceeds the switch capability as does reducing the load resistance.

If the supply voltage is less than 250V then the maximum power occurs
with a load that causes 1A to flow and is now a limit based on
circuit choices and device capabilities.

Note that these power limits have nothing to do with maximum power
transfer in a linear circuit.

Similarly in a tube circuit, the maximum power is limited by the
supply
voltage and the tube drive level (which sets the current that will
flow in the tube). Maximum controlled power is then V*I and occurs
with a load resistance of V/I. Increasing the load resistance reduces
the power because there is insufficient voltage from the supply to
drive more current through the load and reducing the load resistance
reduces the power because less voltage is impressed across the load.

Note that neither of these effects is related to the maximum power
transfer in a linear circuit.

> match.

While a conjugate match does result in a situation where altering
the load will reduce the power transfer, it is not true that any
situation where altering the load reduces the power transfer is
also a conjugate match. The two examples above (bench power supply,
tube in a circuit) amply demonstrate this.

> Keep in mind that the input impedance of the line is complex, or

> reactive, but the reactance of the correctly-adjusted tuning capacitor has introduced the correct amount of the opposite reactance to cancel the reactance appearing at the line input. Thus the line input impedance is R + jX and the output impedance of the source is R =96 jX, providing the conjugate match.

This is quite in error, unless, by happenstance, RL is equal to Rp (plus the other contributors to source impedance).

> You stated in one of your posts that the phase of the reflected wave in relation to that of the source wave results in a non-linear condition. This is totally untrue. The tuning action of the input capacitor in the tank circuit that cancels the line reactance caused by the reflection on the line in no way introduces any non-linearity in the circuit, and the condition in the vicinity of the output of the tank circuit is totally linear. Thus, circuit theorems that require linearity to be valid are completely valid when used with the RF power amplifier as described above. This applies to all RF power amplifiers, Class A, AB, B and C.

For any circuit with a conduction angle of less than 360 degrees, my simulations indicate otherwise. The reflection coefficient experienced by the reflected wave when it arrives at the amplifier output varies with the phase of the reflected wave. Since the reflection coefficient is a function of source impedance and line impedance, and the line impedance is not changing, this means that the source impedance is changing with the phase of the reflected wave. This is not a behaviour that is consistent with a linear circuit. Given the non-linearities in a circuit with a conduction angle of less than 360 degrees, this should not be a surprise. More, it would be a surprise if such a circuit did behave as a linear circuit.

> I hope my comments above assist in understanding the action that occurs in RF power amplifiers.

Thank you. They have indeed helped clarify my thinking.

We are still left with the puzzle of why the observations documented in Reflections report a reduction in power transfer when the load is changed in either direction. It seems unlikely that RL is, by happenstance, equal to Rp, which would be one explanation.

It seems plausible that it is related to the behaviours associated with the examples I provided above, but I can not articulate a mechanism that satisfies.

=85Keith

Sorry, what that means is all you need to do is place the radio near the loop, just like you mentioned earlier. If you want to connect to output of the loop to the antenna input of an AM receiver at some later time, that will work, too. If you don't think you'll use the output from the pickup loop, then skip it for now. You can always add it later if you need it.

Good luck.

tom

Dr. Corum tells us what the problem is: "Lumped circuit theory fails because it's a *theory* whose presuppositions are inadequate. Every EE in the world was warned of this in their first sophomore circuits course. ... The engineer must either use Maxwell's equations or distributed elements to model reality. ... Distributed theory encompasses lumped circuits and always applies."

In particular, *energy flow* is not addressed at all in the lumped circuit model. Some RF gurus are so confused that they imply that there is no Poynting vector power density in reflected waves. Their basic error (for the past 8 years) is that they believe there is no mechanism outside of the reflection model that can redistribute the reflected energy. But what can happen to reflected energy has been known for decades in the field of optical physics. The reflection that one sees in a mirror contains an ExH power density that activates one's human retina. Waves cannot exist without energy. Standing waves cannot exist without forward and reverse traveling waves. That some otherwise knowledgeable and influential RF gurus deny the reality of such is really sad.

What they are missing is simple. The FSU web page describes how wave cancellation redistributes the reflected energy back toward the load from what is essentially a Z0-match. The redistribution of reflected energy due to wave cancellation is technically NOT a re-reflection since it involves destructive interference between TWO waves. When the RF gurus broaden their knowledge base to include wave cancellation, they will alleviate their ignorance on how reflected energy is redistributed back toward the load. That knowledge can be obtained from any good optics reference book including "Optics", by Hecht and "Principles of Optics", by Brown and Wolf. Until those gurus admit to themselves that they are not omniscient, the argument will continue.

> I finished reading Cecil's article (http://www.w5dxp.com/nointfr.htm)

Remember that article describes the two special cases where the two superposed waves are 90 degrees apart and therefore do not interfere with each other, i.e. no wave cancellation exists. I have not yet written the other two articles about constructive and destructive interference.

I have a cheap Sony Dream Machine radio. It has no AM antenna port. SO
the loop antenna should boost its AM reception. That's why I asked. :)

Could FM reception be boosted by the same idea? That Dream Machine radio
has only a simple wire as FM antenna.

Continuing after taking my wife to work:

The reason that optical physicists know so much more about energy transfer than RF gurus is that the optical physicists do not have the luxury of measuring the voltage and current associated with an EM wave at light frequencies. They have historically been forced to deal with irradiance, i.e. power density, at every step of their analysis since that is the only thing they could easily quantize through measurements. As a result, they know everything one needs to know about where the energy goes during reflection and wave cancellation. If one wants to catch up on such as it applies to all EM waves, including RF waves, please obtain a copy of "Optics", by Hecht and read the chapters on superposition and interference. It was an eye opener for me and resulted in my WorldRadio energy analysis article.

http://www.w5dxp.com/energy.htm

Optical physicists usually make power density (irradiance) measurements and then calculate the electric and magnetic fields of the EM wave. RF gurus make voltage and current measurements and ignore energy/power except for net power in and net power out thus losing important details in the process. When they don't understand energy transfer, they dismiss it as unimportant or worse yet, assume that their ignorance somehow proves something as W7EL has done in his "food for thought" article on forward and reflected power. All that he has succeeded in proving is his ignorance of partial or total wave cancellation involving two superposed component waves which can reverse the flow of energy in a transmission line just as easily as can an actual reflection. Here is a diagram of the energy flow at a 50-ohm Z0-match as is common in ham installations.

http://www.w5dxp.com/enfig3.gif

Pref1 =3D Zero =3D P3 + P4 - 2*SQRT(P3*P4)

where P3=3DP4 and the two electric fields are 180 degrees out of phase. This is total destructive interference due to wave cancellation, i.e. out-of-phase superposition.

Pfor2 =3D P1 + P2 + 2*SQRT(P1*P2)

This total constructive interference due to in-phase superposition.

If W7EL would use the general power density equation on his "food-for-thought" examples

Ptot =3D P1 + P2 + 2*SQRT(P1*P2)cos(theta)

he would obtain all the correct answers as to where the reflected energy goes, i.e. the energy analysis would agree exactly with his voltage analysis. That energy analysis would tell us exactly how much reflected power is absorbed in the source resistor and exactly how much is redistributed back toward the load as part of the forward wave. But when W7EL heard these facts of physics from the field of EM wave optics many years ago, he said "Gobbleygook".

But what difference does it make if all external conditions are
identical? If reflected energy is not allowed to reach the source, why
does the source impedance matter at all?

Kraus, Jasik, and Balanis might disagree - maybe even Terman.

Why are antennas a less desirable specialization than any other
specialization? Is counting the barbs on a fruit fly's penis to
determine its exact species somehow superior to antennas? :-)

```

Intelligence is a tool,

Talent is a tool,

But they are not the only tools in the box.

There is drive, there is curiosity, even OCD or Asperger's can be turned into a tool.

There is memory. There is personality.

I'm around 150, but all that means is that if a problem interests me, I can figure it our a little before someone who has a lower number.

Big deal. Some times I think there is something else too, but I'm too dum to put my finger on it. I've noticed that there is something of a troubleshooting skill that I've got/cultivated that often allows me to diagnose a problem a lot more quickly than most other people. Even that's not much help, because I can often figure out a problem in a minute, then spend the next 20 minutes trying to convince the other people I'm with. That's led to some interesting moments, but point is I think there is some ability to compartmentalize mental functions that isn't directly related to IQ.

A fellow who worked for me at one time had a figurative ton of talent. Awesome photographer, highly skilled at tabletop studio photography.

Unfortunately, he had no drive, and his work life was a sad cycle of his talent landing him jobs, and his lack of drive losing them for him.

I've known people with below average intelligence who had other tools
like drive and personality that made them successful, and a joy to work
with.

Hi Keith,

Stripping away everything that you offer as objections to what is not in Walt's premise (I cannot vouch for his attempts to explain the universality of it), your statements come into conflict.

If you offer you find a puzzle about measurements, then that is simply researched at the bench instead of in expansive wanderings in myriad qualifications. Do you have documented measurements under initial conditions identical to Walt's that run counter to Walt's quantitative results?

I suspect not, or we would be talking about competing bench results instead. This would be a more productive and genuine debate seeking explanation for what you describe as the "puzzle."

Barring quantitative evidence, anything that continues this rag-chew is a simple example of "modeling is doomed to succeed."

Hey,
I do not get his lake woebegone on either TV or radio. I seriously
thought he dropped off the radar.

It is only a number and our individual talents can be very different.
I solve a lot of abstract problems and can instantly visualize things
that can and should be improved. It really does not matter here. We were
really just comparing notes, not bragging. I'm sure some on here could
bury me, especially in antenna design. I find that my brain wants a lot
of input so I study various things even though I will never work in
those fields. I'm 61 so why go back to school??
I am a generalist, not a specialist. Curious about many things, and as
you are posting I am still learning about humans reacting to a mere
number. I came on here originally to ask if anyone knew about a noise
blanker that could be inserted into the receiver/antenna, nothing more.
I did expect that most hams are above average, but did not anticipate
any hostility. Don't be so touchy, I came here to learn and possibly
contribute some of my projects and how they turned out.

That does put you at the very least, above average.

That hasn't happened to me, yet.

Same here. Personality makes a huge difference.

Continuing this thought thread - Assuming 50 ohm coax from the source
containing a forward traveling wave and no reflected wave, i.e. an SWR
of 1:1 on 50 ohm coax, what it to prohibit us from drawing our system
box through that piece of coax and considering the signal emerging
from that piece of coax to be the linear source signal which is
obviously associated with a V/I =3D 50 ohm impedance?

Hi Keith,

Sorry, OM, but you still misunderstand various aspects of RF power amp
operation.

First, the power supply is not the limiting factor concerning plate
current. The grid drive is what determines the plate current, and thus
the output power.

Second, the tank circuit is an energy storage device that isolates the
non-linear input from the linear output. That the output is linear is
because the voltage and current are in phase at the output of the tank
circuit. The effect of the energy storage of the tank results in the

tank becoming the source of the energy appearing at the output.

Third, the action of plate resistance Rp occurs only in the formation of RL, and has no further effect on any action downstream of the input of the tank circuit. Thus, it has no bearing on the development of the conjugate match that occurs at the junction of the tank output and the input of the transmission line.

Fourth, as I said earlier, the the action of the bench power supply that you presented in no way models the action of the RF power amplifier. Furthermore, you are incorrect when you say that when varying the load in either direction causing the power deliver to decrease there is no conjugate match. In saying what you did violates the theorem of Maximum Transfer of Power.

Fifth, as I stated earlier, when the reactance appearing at the input of the load (the transmission line with reflections) is canceled by the opposite reactance introduced by the pi-network tuning capacitor, the output impedance of the source (the tank circuit) is the conjugate of the line-input impedance. If you cannot accept this as fact you have a problem.

Sixth, your understanding of the effect of the reflected wave on the source wave is flawed. The non-linearity of the plate current when the conduction time is less than 360=B0 has no relation to the action downstream of the input to the tank circuit, because from that point on the voltage current relationship is linear. If you cannot accept this as fact you have still another problem.

Seventh, your belief that because there is a conjugate match at the output of the tank there must be a conjugate match at the input of the tank is also not true. The effect of the energy storage in the tank isolates the non-linearity af the input from the linear operation at the output, permitting a conjugate match at the output, while not allowing it to occur at the input.

These seven comments are born out (proven) by the results of many measurements I made using laboratory grade instruments, HP and General Radio. If you check my record as a professional electrical engineer regarding the measurements I've made that led to successful hardware flying on various Earth-orbiting platforms, you must accept the validity of the measurements I made on RF power amplifiers that prove my position.

As I said earlier, no one but you has considered my position on this subject incorrect. Therefore, if you cannot agree with the comments I made above, but still consider my statements in Reflections flawed, then there is no point in my making any further comments. I hope someday you'll finally understand what's really happening within the RF amplifier.

Walt Maxwell, W2DU

Hi Richard

> You got on this train rather late if all you see is eight years of it.

I am not mean that!

I clearly said=>

"Always has been a pleasure for me to read you. I have learning very
much from your enthusiastic discussions. You made me think of things
that I never thought without your help. Thank you."

Miguel

Cecil, have forgotten that because the source resistance of the RF
power amp is non-dissipative, none of the reflected power is absorbed
therein?

Actually, this discussion is based on an example introduced by W7EL which assumed a 50 ohm source resistor in his "food for thought, forward and reflected power" article posted on his web page. The source resistance of an actual RF power amp doesn't matter. W7EL's example specified a 50 ohm resistor as the source impedance.

Thanks but my last balun was tossed in the Atlantic Ocean in 1979 and I
will never (ever) use another one. Bill, W9INN, used a center connector
that looked like the W2AU balun in in antennas.

I worry that the W2AU may be more than a center conductor

Hi Cecil

> Continuing after taking my wife to work:

Yo have a chopper, I have a chopper. Your wife go to work, my wife go
to work. Are you my big brother? (older brother? =3D> "hermano mayor",
in spanish) :>D
...
> Dr. Corum tells us what the problem is: "Lumped circuit theory fails
because it's a *theory* whose presuppositions are inadequate.

Well... "theories" are theories, models of "reality". As Einstein
said: "free creations of the human mind" =3D> Newton's gravity theory,
Einstein's gravity theory...
Einstein one of course it is more accurate in certain situations, but
we still using Newton's laws to send spacecrafts to Mars. As in the
Sears-Zemansky example given, they coexist and it can solve differents
problems.
Velocity adding fails at very high speeds ("presuppositions are
inadequate") and we need relativity, but for common situations it is
not necessary use the last one (of course you know it, it is only a
note). It is easy for us become tempted to think that Einstein one it
is the "true" theory and not "a better aproximation to reality"
theory.

As some of us agree "all models are false", then, perhaps --only "perhaps"-- (I do not want offend to anyone) some of the others models presented by our distinguished colleages could not be as precise for certain special situations, but still quite adequate to solve problems or explain more simple things, as a Newton laws or "charges in movement"...

As in other physics laws, it is not possible to reach a similar consensus here in this regard? Models given, leads to wrong numbers or failed to agree with empiric data?

Your examples, Cecil, gve me a light, now I have in my mind three models that (for me) describe "reality" so good. With yours I can think in forward and reflected power flowing simultaneously on Rs -not contradiction-
Adding phasors of the forward and reflected travelling waves before the last one reach generator, this one sees different Z line input and not any reflected power there is circulating on it (not contradiction to me) =3D> "adding" in my human mind, of course. Reality only God/Allah/Yahweh/Manitou/The Force/Zeus, knows- :>) .

I'm not trying to be syncretic. Same cat, different models... Is it not possible that?

Hi Miguel,

You are welcome.

My comments (beyond your quote above) were in regard to you observing the amount of time Walt's topic has been under discussion. In fact, the agony of source resistance has been painfully with us for as long as newsgroups could support the noise bandwidth.

As dangerous as unasked-for advice is, prepare something at your bench to measure all these contentious issues for yourself. Force the issues that are only being discussed rather than measured. Discover the roots of what used to be a "hands on" avocation. Learn the practical reality in relation to the academic meaning. Discover the first principles by making mistakes and having failures that you can correct in front of you, instead of being assisted by an "expert." Compare results with like-minded bench workers who can perform the same examinations you are doing.

This is what Walt did - many times. His bench work eclipses ALL discussion of theory. The irony that inhabits this is that his bench work may even eclipse his own explanations. Absolutely no one else has dared to slide up to the bench to demonstrate that, however. The level of "critique" is much like ants scattering at the feet of a giant.

There is a lot of math thrown against the wall to prove something. It may or may not be the same thing. What it does prove is:
"Models are doomed to succeed."
This is demonstrated here at least once a week on average, and is even held up as a hallmark of hazing, initiation, or anti-intellectual snobbery. Math/Models/Simulations/Theories serve many religious wars.

Keith Dysart wrote:
"For the most part, "maximum power transfer is just an interesting
ideosyncracy of linear circuit theory."

In the world of 50 and 60 Hz, we don`t want all the power plant can
supply when we flip on a light switch.

The RF world is usually different.

Maximum power transfer only occurs when source and load match
conjugately, and the match proves the load and source impedances are
equals. It is well known and easily shown that a match results in
maximum power transfer.

If one has a 100-watt transmitter he probably wants 100 watts out of it
sometimes and may only be able to do so when his antenna is matched to
his transmitter,

Maxumum power treansfer is more than an "interesting ideosyncracy".

Best regards, Richard Harrison, KB5WZI

It's also easily shown that it doesn't.

Consider a 10 volt voltage source having a 50 ohm source resistance,
feeding a 50 ohm resistive load. Power at the load is 0.5 watt, is it not?

Reduce the source impedance to 10 ohms.

Now what is the power dissipated in the load?
Is it greater or less than it was when the source and load impedances
were matched?

Roy Lewallen, W7EL

Yes, except that W7EL uses the inadequacy of his model to prove that
his model yields contradictory results. I freely admit that his model
is inadequate and contradictory which implies that he is using the
wrong model.

unfortunately bill, art suffers from short memory also among his other
debilities.  it has been explained to him several times by different
people that gauss'es law is perfectly applicable to both static and
varying fields without his 'improvement', he just can't remember it
from day to day.

I don't know Cecil, he may be correct.  Who needs TV, radio, cell
phones, satellites, WiFi and other crap like that?

tom

> First, the power supply is not the limiting factor concerning plate current. The grid drive is what determines the plate current, and thus the output power.

Of course the grid drive is one of the factors which controls the current flowing in the load.

But the power supply is also one of the limiting factors. Reducing the power supply voltage below that which is necessary to cause the desired current to flow in the load will reduce the power output. Similarly, increasing the load resistance will eventually raise it to the point where the voltage is no longer adequate to cause the desired current to flow.

> Second, the tank circuit is an energy storage device that isolates the non-linear input from the linear output. That the output is linear is because the voltage and current are in phase at the output of the tank circuit.

Can one not have a linear circuit where the current and voltage are not in phase? Also, if one loads any tank circuit with a resistance, the output current and voltage will be in phase and if it is loaded with a reactance, they won=92t be.

> The effect of the energy storage of the tank results in the tank becoming the source of the energy appearing at the output.

Yes, but that does not make the output independent of the input.

> Third, the action of plate resistance Rp occurs only in the formation of RL, and has no further effect on any action downstream of the input of the tank circuit. Thus, it has no bearing on the development of the conjugate match that occurs at the junction of the tank output and the input of the transmission line.

I do not understand what is being said here.

> Fourth, as I said earlier, the the action of the bench power supply that you presented in no way models the action of the RF power amplifier. Furthermore, you are incorrect when you say that when varying the load in either direction causing the power deliver to decrease there is no conjugate match. In saying what you did violates the theorem of Maximum Transfer of Power.

The definition I use for conjugate match is one where the source impedance is the complex conjugate of the load impedance. When this situation occurs between linear networks, maximum power is transferred between the networks.

None-the-less, just because maximum power is being transferred between two networks does not mean they are complex conjugates of each other.

This is demonstrated with the non-linear behaviour of the bench power supply example. Maximum power is transferred but the source and load impedance are not complex conjugates.

> Fifth, as I stated earlier, when the reactance appearing at the input
> of the load (the transmission line with reflections) is canceled by

> the output impedance of the source (the tank circuit) is the conjugate
> of the line-input impedance. If you cannot accept this as fact you
> have a problem.

Perhaps I am not computing the impedances correctly. Let us see if I have done so for the following example.

Consider a generator constructed of current source in parallel with a resistor, driving a PI network, connected to a load.

```
         generator               filter          load
                                 6.945uH
       +-------+-------  ----+---/\/\/\/---+----  ---+
       |       |             |             |1.398    |
     +---+     \             |             | nF      \
3.75 | I |     /8000       -----         -----       / 50 ohm
 MHz |   |     \           -----         -----       \
     +---+     /             |295.5        |         /
       |       |             |  pF         |         |
       +-------+-------  ----+-------------+----  ---+
```

Looking into the input of the filter, then impedance is 1500 ohms. This is the load applied to the generator and is computed by applying the rules for series and parallel components to the 50 ohm load, and the two capacitors and inductor in the PI network.

It is, I hope, generally accepted that the generator will have an output impedance of 8000 ohms.
The output impedance of the filter is computed by applying the rules for series and parallel components to the 8000 ohm generator impedance and the 3 components in the filter.
The result is 58.00 /_ 68.60 ohms.

Note that the component values were taken from a PA design where the desired load for the tube was 1500 ohms. And 8000 is not an unreasonable slope for the plate E-I curve of a tube.

This has not resulted in a conjugate match.

> Sixth, your understanding of the effect of the reflected wave on the
> source wave is flawed. The non-linearity of the plate current when the
> conduction time is less than 360=B0 has no relation to the action
> downstream of the input to the tank circuit, because from that point
> on the voltage current relationship is linear. If you cannot accept
> this as fact you have still another problem.

It is, perhaps, this claim of isolation that is most strange. It seems quite at odds with the rules for connected networks.

> Seventh, your belief that because there is a conjugate match at the output of the tank there must be a conjugate match at the input of the tank is also not true. The effect of the energy storage in the tank isolates the non-linearity af the input from the linear operation at the output, permitting a conjugate match at the output, while not allowing it to occur at the input.

It was my understanding that in a sequence of connected linear networks, if any connection exhibited a conjugate match, then they all were conjugately matched. Is this not correct?
Are you saying that if a conjugate match is present between the line and the antenna, it might not be present between the transmitter and the line?

> These seven comments are born out (proven) by the results of many measurements I made using laboratory grade instruments, HP and General Radio. If you check my record as a professional electrical engineer regarding the measurements I've made that led to successful hardware flying on various Earth-orbiting platforms, you must accept the validity of the measurements I made on RF power amplifiers that prove my position.

I quite believe your measurements. It is the conclusion that they prove a conjugate match that I find impossible to accept. Both because there are other situations that can lead to power behaviours that may appear similar to the power behaviour of a conjugate match and the method proposed for computing source impedance is quite at odds with linear theory.

But the quality of the measurements suggest it is worthwhile to explore other explanations.

But Roy, consider that the source resistance remains constant at 10
ohms. Then what load resistance will absorb the most power? The answer
is 10 ohms. Any value of load resistance greater or less than 10 ohms
will result in less power delivered. I don't believe it's fair to
```

change the source resistance when dealing with the Maximum Power Transfer Theorem.

In your example with a source resistance of 10 ohms and a load resistance of 50 ohms the power delivered will be 1.39 watts. But when the load resistance is 10 ohms with the same source resistance the power delivered is 2.5 watts. As I said above, if the load resistance is either greater or less than 10 ohms the power delivered will be less than 2.5 watts. Thus when the source resistance is constant the maximum power will be delivered when the load is matched to the source.

Nes pa?

Walt

I see no hostility from you Bill. But there has been a lot of hostility to my proposed theorem. Just following Newtons laws for equations that when all is summed it must equal zero. This is no different that allowed an addition of displacement current by Maxwell. Same goes for all boundary laws with respect to Newton whether they may be static or dynamic. Now in the case of Gauss and Newton each had different units because of a change in standards so authors never bothered or was to lazy to do the excercise. As it happens if one did go thru with the excersise you will find that the dynamic form of Gauss's law is exactly the same as Maxwells laws for propagation. Just think if any author had taken this step we would never have had the discussions of waves versus particles that have held up the explanation of accelleration of charge which is propelled by the intersection with displacement current! This group initially rejected everything because I inferred the connection of static fields with propagation which they just could not accept. And for good reason in that it is not explained in any books. When I used an optimizer program based solely on Maxwell I expected an array in equilibrium which is what I got. In addition the array supplied by the program reflected the equal and opposite arrangement of vectors supplied by gravity and earths rotation where these same two vectors continue thru out the Maxwell /Gauss equation all the way back to the big bang when equilibrium was broken momentarily where a particle escaped with the addition of spin. All this was what Einstein was searching for and showed how a particle/charge was supplied with accelleration and spin such that there was straight line trajectory that was not impinged upon by gravitational effects. From all these matching sections and interactions I saw that the Neutrinos was the particle in question because it is of the smallest mass known and because of this the speed of light can be ascertained. Now we have the accelleration of the neutrinos (CERN and FERMILAB) and consequential impacts which sort of infers that the neutrinos can shatter into smaller amounts of mass of that which was accellerated at the speed of light which I really don't understand. We also have the notion of a photon detaching itself from a Neutrinpos for the purposes of light which states that this aproach means the formation of a photon that has no mass the possibility of which has not been proved. Frankly physics has to go back to classical physics where it is confirmed that the idea of waves was an error that held physics back for so long. At least now we have a progresion of events that satisfies Maxwells equations in every respect that requires no new laws and only the adherence to existing laws of the masters where the presence of equilibrium is demanded as with all laws. The cream of the theory came when I used a program devoted solely to the requirements of Maxwell and it provided a non planar design where equilibrium was adhered to and the vectors involved were opposite to those involved outside the boundary containing our Earth.

Best Regards

> change the source resistance when dealing with the Maximum Power
> Transfer Theorem.

>
> In your example with a source resistance of 10 ohms and a load resistance of 50 ohms the power delivered will be 1.39 watts. But when the load resistance is 10 ohms with the same source resistance the power delivered is 2.5 watts. As I said above, if the load resistance is either greater or less than 10 ohms the power delivered will be less than 2.5 watts. Thus when the source resistance is constant the maximum power will be delivered when the load is matched to the source.
>
> Nes pa?
>
> Walt

Of course, I know that, and I would hope anyone with even very basic electrical circuit analysis knowledge does. And anyone with that knowledge should state as you have,

"FOR A GIVEN SOURCE IMPEDANCE, maximum power transfer occurs when the source and load impedances are matched (i.e., the load impedance is the complex conjugate of the source impedance)," which is true.

But the statement which was made was that "Maximum power transfer occurs when the source and load impedances are matched." This is NOT true, as the example demonstrates.

It's an important distinction. Instead of declaring what's "fair" and what isn't with regard to changing source and load impedances, the maximum power transfer theorem should be stated correctly, in a way which makes it true.

Roy Lewallen, W7EL

st�tic bound�ry dyn�mic such th�t M�xwells l�ws were �pplic�ble. This
immedi�tely showed th�t p�rticles
�nd not w�ves were the c�rriers of prop�g�tion.

No waves without particles.
Sound waves are the vibrations of air partiles (or liquids and solids).
Water waves are movements of water paeticles.
Electric waves are the vibrations of electrons.

In Maxwell's hypothesis EM waves are the rotational oscillations of massive
magnetic substance.
Up to now the massive magnetic substance is not detected. After Maxwell's
death the electrons were discovered.
Heaviside's equations describe the Maxwell's waves geometrically.

>We �re � very old group th�t h�s lived long on the ide� th�t w�ves
were the c�rriers of prop�g�tion so �ll �re fighting like hell �g�inst
ch�nge. So �ll h�ve c�me up with the ide� th�t it is illeg�l to
tr�nsform � st�tic field into � dyn�mic field bec�use nowhere is it st�ted
in

If you are uninterested in source impedance (and many people seem
to be much more concerned with it than they need to be), then
by all means do not consider it, do not specify it, do not attempt
to compute it or measure it and do not make statements about what
the source impedance is.

But if source impedance is of concern for a particular application,
then please do compute and measure it properly.

you have a nice little web site, please publish the design file and
picture of the antenna so we can all have a good laugh at it.

no, you still can't say that... the equation still applies to fields
just like it always did.

The theorem requires linear *lossless* networks which do not exist in reality, i.e. networks containing only reactances. Therefore an *ideal* system-wide conjugate match cannot exist in reality just as a lossless transmission line cannot exist in reality. In low-loss systems, we can only achieve a system-wide near-conjugate match with an ideal conjugate match existing at one point, e.g. the Z0-match point where reflected energy flowing toward the source is eliminated.

> Are you saying that if a conjugate match is present between the line
> and the antenna, it might not be present between the transmitter and
> the line?

Yes, speaking for me, in the real world, it is easy to prove that the system-wide impedance looking in one direction is not always exactly the conjugate of the impedance looking in the other direction. Thus the "maximum power transfer" assertion has to be modified to "maximum *available power* transfer". In the real world, ohmic and dielectric losses reduce the power available to be delivered to the load.

It's easy to see. Let's say we have a completely flat 50 ohm system; 50 ohm source, 50 ohm coaxial feedline, and 50 ohm antenna. Now assume we install an antenna tuner between the source and the feedline that exhibits some series impedance and we adjust the tuner such that the source sees 50 ohms. At the output of the tuner looking toward the antenna, we will see 50 ohms. Looking back through the tuner toward the source, we will see the tuner impedance in series with 50 ohms. That proves it is not an *ideal* (lossless) conjugate match although it may be considered to be a near-conjugate match, as close as we can come in the real world.

What I don't know is how close a real-world conjugate match has to be to an ideal lossless conjugate to be called a "conjugate match". A purist might argue that an ideal conjugate match cannot exist in reality. A realist might argue that if we are within 10% of an ideal conjugate match, then it is a real-world conjugate match, by definition.

Note that I am not speaking for Walt here, just for myself.

```

The question then becomes: If the system box does not include the source and the system exhibits characteristics consistent with a conjugate match, can we say the system is conjugately matched? For instance:

100V---50 ohm coax---+---1/4WL 300 ohm feedline---1800 ohm load

This system exhibits all the characteristics of a conjugately matched system. Can we say it is conjugately matched?

Excuse me Cecil:

I am reading this newsgroup through Google groups web page and I just realized that later replies to previous post are intercalated in the thread, while I expected to see it always at the end of it, for that reason I did not ACK before to it. (I hope yours be the only one, I will review all thread tho chek for others).

In a early post I wrote =3D> "of course if we insert a circulator to separate both powers, generator now would see 1 ohm load, could develope 1 W incident, 0 W reflected (Pn=3D1W) on circulator input, 0.36 W would be outputting on the other port to render 0.64 W (Pn) to the load with 1 W Pf and 0,36 W Pr again"
Is this result OK for you?.

The thread advance toward more deeper issues since :>), and now I have been analizing all the matter because it quickly superceed my original doubt. A few minutes ago had started to read your article (http://www.w5dxp.com/energy.htm) and the Roy's one (http://eznec.com/misc/Food_for_thought.pdf) and yesterday I have been reloading my old "Transmission lines antennas and wave guides" from King, Mimno & Wing to review the issue from that classical perspective.

I am interested in your optic analogy, I can imagine the load as a partially reflecting surface, real part of it as absorbance (transmittance if it was a radiator). line as a unidimensional medium and reflection as the form of "redistribute energy" (is it OK?) and a coherent light source for the voltage source, but I am still trying to visualze the optical equivalent of source resistance and its job to be a good analog, Also I am interested in check other values and conditions in your other article (first part) with 45 degree line.

Thank you very much for your helping and inspiration.

73 - Miguel LU6ETJ

Nope, what we can say is that waves and their associated particles are
dual manifestations of the same physical phenomena. There is no

difference between an EM wave and a photonic wave and individual photons exhibit electromagnetic wave properties. What is important is that one can double the energy magnitude by adding, in phase, one photon to one photon. But one cannot halve the energy magnitude by cutting a photon in half.

It is easy to identify individual photons in an EM wave, especially at the higher (light+) frequencies. Not so easy is identifying individual photons in the static magnetic field from a permanent magnet. :-o

I am also using Google since ATT dropped Usenet. I liked Thunderbird a lot better than Google's usenet interface but I am adapting. The above information is good to know. Thunderbird has a way to keep up with unread vs read postings but Google doesn't seem to - at least I don't know how to do it on Google.

> In a early post I wrote =3D> "of course if we insert a circulator to separate both powers, generator now would see 1 ohm load, could develope 1 W incident, 0 W reflected (Pn=3D1W) on circulator input, 0.36 W would be outputting on the other port to render 0.64 W (Pn) to the load with 1 W Pf and 0,36 W Pr again"
> Is this result OK for you?.

The SGCR source is usually designed for 50 ohms, i.e. the signal generator always "sees" a 50 ohm load because it does not "see" any reflected energy. The ideal circulator is usually designed with 50 ohm line and a 50 ohm load resistor. If we could stick with that particular configuration for the SGCR source, it would aid in my understanding what is the actual system configuration, i.e. not your fault but I am confused by your above posting.

> I am interested in your optic analogy, I can imagine the load as a partially reflecting surface, real part of it as absorbance (transmittance if it was a radiator). line as a unidimensional medium and reflection as the form of "redistribute energy" (is it OK?) and a coherent light source for the voltage source, but I am still trying to visualze the optical equivalent of source resistance and its job to be a good analog, Also I am interested in check other values and conditions in your other article (first part) with 45 degree line.

I don't think a laser source handles reflected energy like an RF amp does. So, to start with, let's avoid reflected energy being incident upon the laser source. Here is a good example to start with, a 1/4WL non-reflective coating on glass.

Laser-----air-------|--1/4WL thin-film, r =3D 1.2222---|---Glass, r =3D 1.4938---...

The 1/4WL thin-film coating on the glass acts exactly like a 1/4WL matching section of transmission line. Reflections at the air to thin-film interface are eliminated by wave cancellation just as the FSU web page says,

micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the photon energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so

the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

Note that the reflection coefficient, r, is 1.0 for air. Thus the
SQRT[(1.0)(1.4938)] =3D 1.2222 ensures that reflections are eliminated
by the r =3D 1.2222 thin-film coating.

The same thing happens at the '+' Z0-match in the following RF system.

```
XMTR---50 ohm coax---+---1/4WL 300 ohm feedline---1800 ohm load
```

Note that SQRT[(50)(1800)] =3D 300 ensuring that reflections are
eliminated.

> Also I am interested in check other values and
> conditions in your other article (first part) with 45 degree line.

Sorry, I forgot to comment on this. If the line length is fixed at 45 degrees, the reflected wave arrives back at the 50 ohm source resistor 90 degrees out of phase with the source's forward wave. When two waves are 90 degrees out of phase, there is zero interference between them because cos(90) =3D 0 and the interference term in the following equation disappears.

Ptot =3D P1 + P2 + 2*SQRT(P1*P2)cos(theta)

There is no re-reflection of the reflected wave from the 50 ohm source resistor because it matches the coax Z0. There is no redistribution of constructive/destructive interference energy because there is zero interference. Therefore, for the special case where Vfor is 90 degrees out of phase with Vref at the source resistor, all of the reflected power will be dissipated in the source resistor.

If the interference at the source resistor is constructive, i.e. less than 90 degrees difference between Vfor and Vref, the power dissipated in the source resistor will be all of the reflected power plus some of the source power.

If the interference at the source resistor between Vfor and Vref is destructive, i.e. between 90 degrees and 180 degrees, some of the reflected power will be redistributed (by wave cancellation) back toward the load.

Note that the I and Q method of transferring two streams of information on the same carrier relies on this same no interference (at 90 degrees) concept.

> such that there was straight line trajectory that was not impinged
> upon by gravitational effects.

I am wondering how a wave, light, can be affected by a black hole as has been seen by the Hubble space telescope. This goes deeply into the nature of light it self, like how is a wave with no real mass affected? We need researchers pushing the boundary, and if others don't understand it then let them step aside.

From all these matching sections and
> interactions I saw that the Neutrinos was the particle in question

> means the formation of a photon that has no mass the possibility of
> which has not been proved.

This is where I get into it, Photons are just a way to explain something to the masses of people who can nor understand the true nature of light. CERN has, I think, two counter rotating beams that can cause a crash at nearly twice the speed of light.
New and non-naturally formed particles, some with a life time measured in nano seconds.

Frankly physics has to go back to classical

Photons have mass because of their velocity (speed of light). m =3D E/
c^2 Photons have no rest mass but they are never at rest. An
experiment long ago proved Einstein to be correct when he claimed that
light was affected by gravity. A black hole is no exception.

http://en.wikipedia.org/wiki/Gravitational_lens

> Frankly physics has to go back to classical

How would classical physics explain how a single particle can go
through two slits at the same time and interfere with itself on the
other side? This phenomenon includes photons, electrons, and
apparently includes relatively massive Bucky Balls made up of many
carbon atoms.

How would classical physics explain how entangled particles remain in
instantaneous contact no matter how far apart they are? This seems to
violate the spirit (if not the letter) of the speed-of-light limit.

FYI, It appears that Google has a "Reader" available at the top of the
web page, that has the mark-as-read/unread ability with which one can
keep track of the read/unread postings.

I probably should not have breached the subject since it will be a war
of opinions. If light was indeed a particle (photon) it could be
affected, but light is just really super high frequency radio in nature.
Radio is not particulate so why the hang-up over photons???

And are this true: "We also assumed, perfectly arbitrarily, that the direction of these vortices is such that, on looking along a line of force from south to north, we should see the vortices revolving in the direc- tion of the hands of a watch. We found that the velocity of the circumference of each vortex must be proportional to the intensity of the magnetic force, and that the density of the substance of the vortex must be propor- tional to

the capacity of the medium for magnetic induction." From:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

"the density of the substance of the vortex "
As you see in Maxwell's hypothesis was the mass. The all waves need mass and
inertia.
But all movements (also waves) can be described dynamically (with mass) or
geometrically (only directions and speed).
The famous Heaviside's equations are the geometrical description of the
waves.
S*

Roy Lewallen, W7EL wrote:
"Nut the statement which was made was that "Maximum power transfer
occurs when the source and load impedances are matched."

Inelegant and bereft of qualifications as it may be, I am the author of
that statement, and I stand by it.

Roy says: "This is not true, as the example demonstrates."

Robert L. Schrader says on page 43 of "Electronic Communication":
"To produce maximum power in any load, it is necessary that the load

resistance equal the internal resistance of the source."

I believe our statements are equivalent. Load a battery of a given internal resistance with the same resistance as a load, and for a short time the battery will deliver more power to that load than to any other resistance larger or smaller.

Best regards, Richard Harrison. KB5WZI

Quoting Roger Miller from the movie: "Water Hole Number Three"; "If fishes had wishes, they'd fly".

Actually, it has nothing to do with opinions and everything to do with actual experiments. EM wave energy, which includes visible light and RF waves, has been proven beyond any doubt to be quantized which implies a particle nature and not a continuously variable analog field. In fact, quantum electrodynamics, which has an uncanny ability to predict sub-atomic physics experimental outcomes, tells us that nothing can exist outside of its existence as a particle. Have you ever tried to prove that something can actually exist without a particle nature being involved?

From the lowest level of light detectable by the human brain, the next step up in brightness is 11.1111% greater than that first level - not 0.000001% as your opinion seems to desire. Following is the URL for an interesting paper on the subject.

I downloaded the pdf file so I can read it this evening. I may be back
on this topic later after doing some reading. Of course I may disagree
with the particle nature, but hey, I have an opinion too.
Cheers,
Bill Baka

as has already been pointed out this paper predates the publication of
the full set of maxwell's equations, and even the publication of
gauss' law... so much development was done in em theories after that
date. just because something is written down doesn't make it right or
we would still be living with 4 elements and letting blood to cure
disease.

 The folded dipole with 1:4 baloon is best  solution for maching
yagis .

Over the last few years a I have started preferring using the folded
dipole for the  driven element also. I dont understand your need for
4:1 BALUN though.

Jimmie

```

I stand by my position that when the source is an RF power amplifier, and when all the available power is transferred from the source to the load, the source impedance is the conjugate of the load impedance. In a similar instance, if the load is a pure resistance, the source resistance equals the load resistance.

And referring to a statement Dysart made concerning plate resistance, Rp, it must be understood that in Class AB, B and C amplifiers, Rp is NOT the source resistance. In those amplifiers the effect of Rp is a negative feedback that reduces the effect of plate-current change resulting from a change in grid voltage, thus reducing the power output compared to what the output would be if Rp were absent. Compensation for the power lost to Rp is accomplished by simply increasing the grid drive.

Consequently, Rp plays no part in achieving a conjugate match at the junction of the network-output and the load. Although lossless elements are required to achieve a perfect conjugate match in both directions, a perfect conjugate match is obtained in the forward direction with real elements when all available power is being delivered to the load. This condition is verified in data presented in Chapter 24 of Reflections 3.

Walt, W2DU

another robust one is the T match as used in old telrex yagis.  it is
dc grounded and needs no capacitor, but it does use a 1/2 wave 'balun'
or phasing line between the halves of the T.

Meanwhile I study carefully your reply and investigate the Google
Reader (thanks for tell me) tell you that one ohm examples are only
because I often work with normalized impedances. I will move me to 50
ohms neighborhood... :>)

I'll give you a partial agreement on this one. The rods in our eyes have
peak sensitivity at Yellow/green. There was a guy, a long time ago who
said he could detect a single photon in a very dark lab. So, if a photon
is anything anyhow a particle how could he see it since the equipment
was set up to radiate into a detector. It may not be in our lifetimes
that the true nature of light is discovered.

The cones cannot detect single photons. It takes many photons to
activate the cones. It only takes one photon to activate a rod.
Unfortunately, the rod is more sensitive than the rest of the path to
the brain so it takes about 9 photons to result in  an impulse to the
brain.

Just use the dipole as is on 160. I had basically the same setup with 63
foot legs on
an inverted vee and worked plenty of 160 stations.  Try it -- if you don't
find it
satisfactory, then you can always try something else. System degradation is
usually
far less than theory would have it.

I thought everyone on this group would know that. That is also why some
animals can see in the dark, no cones, but all rods in their eyes.

Now be sure to tell the researcher that. I give up on this subject,
since you all have been trained to believe that there is such a thing as
a photon. It reminds me of religious indoctrination.

```

Hi all. I have a doubt about if this text from "Another look at reflections" reflect the author ideas.

"Laboratory and experimental work often requires holding incident voltage constant with variation in loading. A constant-voltage source is usually obtained for this purpose by inserting a pad having 15 to 20 dB attenuation between the generator and the line to absorb the reflected power, preventing it from reaching the generator where it would alter the line coupling and cause the generator output voltage to vary. Because of the absorption of the pad, the generator sees a nearly perfect match for all load conditions and all reflected power is lost - but these are laboratory control conditions required to obtain valid test data."

For example this part =3D> "by inserting a pad having 15 to 20 dB attenuation between the generator and the line TO ABSORB the reflected power"

=BFAbsorb the reflected power or amortiguate the effects of variyng load impedance?

As I understand it, even without a conjugated match the reflected power neither returns to the source (Thevenin equivalent source).

I give the following example: If we load a generator directly with a resistance of 10 ohms, without any transmission line, there are not

traveling waves interfering, therefore there are not stationary waves,
there is only a impedance mismatch affecting the source voltage =BFOK?.
If then I load it with a line of half wave finished in the same 10
ohms resitance, the generator "will see" a 10 ohms load, and it will
behave identically as it made it with the original "direct" load.
In both cases there is not reflected power that it can return to the
generator...

(I admire Walter's work and this consultation should only be read as a
question, not as a criticism)

Thank you very much in advance.

Miguel Ghezzi LU6ETJ

I would not refer to the cascading of a practical source with a 15 to 20dB attenautor at a 'constant-voltage source' as Walt did above.

A Thevenin source with Zs=50+j0, with varying load impedances, will always have terminal v/i such that the Vfwd component of a traveling wave decomposition of v is constant. I give the explanation / proof at http://vk1od.net/blog/?p=1028 .

Even if a given source has Zs not equal to 50+j0, a sufficiently large cascaded 50 ohm attenuator will result in a combination that is very close to the ideal Zs=50+j0, albeit at lower level. This is a common technique for 'standardising' the equivalent source impedance of a source.

Owen

That is how it works. They have to produce some results for their
funding to continue. I remember when they tried to explain that
everything was made up by quarks. That could possibly explain Neutrons
and Protons, but what about that poor little electron??
Also how come a puny electron has such a charge that it roughly equal
the charge on a (relatively) huge Proton??
There is a lot of understanding to be done yet.
1. What is the speed of gravity?
2. How does gravity propagate through seemingly empty space?
3. How can a magnet attract in the vacuum of space?
Many more questions than answers.

I don't think those questions will be solved until the median IQ reaches
about 130 and not 100, but I am not holding my breath over that ever
happening.
Something for people to think about.
Bill Baka

Hi Brian:

When dipoles are mounted to the side of a tower or metallic support, the gamma match allows the impedance matching to a 50 ohms transmission line at the optimal distance from the mast to obtain the typical diagram of the "ofsset." configuration.
To adapt the folded dipole impedance only appealing to a 4:1 transmission line balun it is necessary to bring them near enough to the tower or conductive mast and so the radiation diagram is no longer the one that habitually we imagine (+9 dB front, 3 dB back).

Thank you for your answer Owen (but I think that it doesn't answer my specific question, possibly because I am not able to express it well due to my translation to English).

.....

I agree with what you say in your answer and several things you write in your good article "Is Zs of to HF ham tx typically 50+j0? ".

For example that for an idealized Theveninj generator, the incident power is independent of the load impedance (net power Pf-Pr not) (If an impedances adapting device is inserted between the line and generator and we insert directional wattmeter between the matching device and line, of course Pf varies and Pnet also do it).

Regarding that output impedance of a rig be quite near to 50+j0 I think that depends on the concrete design; such a condition is not necessary and in my opinion neither optimal.

Best regards

Miguel Ghezzi LU6ETJ

I spoke to some physicists at the Fermilab accelerator at Batavia ILL
a few weeks back and it was surprising to me how often the statement
was made "that is out of my expertize". Seems like they are trained to
think in a tunnel out of the hearing and contact of others.Considering
the amount of funds they collect their sparse achievements as noted in
their weekly news letter sure does not impress me a bit. How many
times have we heard
"we hope that "if" we are successful it is possible that it could lead
to........"I look for a barrage of such statements in the future about
the difficulties of finding Higgs field where it is now felt to be of
```

virtual form without mass and possibly out of range!

Hi Miguel,

Problems arise from qualitative statements or questions instead of quantitative statements or questions.
>output impedance of a rig be quite near to 50+j0

is a quantitative fact (depending upon the qualitative "near"). A fact can be measured and compared by in dependant and objective means.
>in my opinion neither optimal

is a qualitative judgment. A judgment is only as authoritative as is the authority making it - and even then it comes at a discount. We get many judgments here by folks with little authority (and such judgments are usually adorned with anti-authority messages).

I have measured the characteristic Z of my two transistorized HF rigs by different methods that agree in their results. I have also measured the Z of active loads that employ the same circuitry found in power sources. The values of Z for my HF rigs wander from 35 Ohms to 75 Ohms. The variation is a function of
1. frequency;
2. power;
3. which of the two is being measured.

What is notable, for those values that are furthest from 50 Ohms (the design goal), my rigs experience issues (instabilities, poor efficiency, distortion...).

The variation by frequency is found at the margins (at the ends of the HF band).

The variation by power is found in inabilities to maintain a constant power deliver in every band - which weakly correlates to Z offset from 50. Variation by power also defines Z. Low power operation is not going to give you a 50 Ohm source (the manufacturer designs Z for rated power).

The variation by set is due to different capabilities: one set is capable of 150W, and the other 100W; thus the first is more robust. As these variations of Z are not remarkable, trying to turn them into quantitative efficiency results are speculative at best (common designs are not optimal by any stretch when you add in the complication of modes).

This resolves quickly in measurement - no need to wonder unless it offers some secondary benefit of not measuring things.

An alternative is to simply examine conventional design considerations. One can add to Plate current by throwing a lot of power into the grid. More plate current yields more output power results, but grid lifetime plumments.

One can do innumerable things to force an artificial outcome that strains to prove a distorted logic. Examining a suite of sources, in initial conditions that are average for their application quickly reveals a common design paradigm.

******

The fundamental answer to your question is the manufacturer ultimately designs for market domination, or maximum investment return (the two don't necessarily converge). Thus the marketplace gives us a spectrum of choice and the norm of the distribution reveals cautious design that has its eye on a value exchange expressed in money. THAT is the only optimization you can expect = in an honest barter, you get what you pay for.

On May 24, 10:55=A0am, walt <w...@w2du.com> wrote:

> Keith, would you please elaborate on why you believe my analysis of transmitter output impedance is flawed? And what is the basis for your belief that my explanations in Reflections require large chunks of linear circuit theory to be discarded. Could it be because you consider the source resistance in the transmitter to be dissipative, as in the classical generator? If so, you must be made to realize that the source resistance of the transmitter is non-dissipative, which is the reason that its efficiency can exceed 50%.

No problems there. There has been much confusion in this area and anything that reduces this confusion is beneficial.

> Or are you considering the output characteristic of the transmitter to be non-linear? This is not the case, because the effect of energy storage in the tank circuit isolates the non-linear input from the output circuit, which is linear as evidenced by the almost perfect sine wave appearing at the output of the tank.

This may be the root of my disagreement. Certainly the output can be an arbitrarily perfect sine wave, but this simply depends on the characteristics of the filter and not on whether the system is linear.

But the way the filter transforms the impedances is the crux of the issue.

It is my understanding that the input impedance to a filter can be computed by starting with the load impedance applied to the filter and then, using the rules for series and parallel connected components, compute the way through the filter until reaching the input and the result is the input impedance to the filter.

Similarly, the output impedance of the filter can be computed by starting with source impedance driving the filter, series and paralleling the components until reaching the output and the result is the output impedance of the filter.

The desired impedance for the input to the filter is that impedance which produces the desired load on the tube. And the component values are computed to produce this load on the tube when the correct load is attached to the output.

For the output impedance of the filter, the question then becomes: What is the source impedance driving the filter? If the source is constructed as a Class A amplifier, then it depends on the controlling device, and for the simplest of circuits would be Rp of the tube. (Just for clarity, in this discussion Rp is the slope of the plate E/I curve with constant grid voltage. In an ideal tube, these lines are equidistant apart and the slopes are the same. Real tubes, of course, are not so well behaved, but this should not affect the basic discussion.)

Since the component values for the filter were chosen to provide the optimum load to the tube, and the optimum load value has no relation to Rp, there is no reason to expect the filter will transform Rp to be the conjugate of the load impedance.

For amplifiers where conduction is not for 360 degrees (Class AB, B, C), the controlling device is no longer time-invariant so the rules for linear circuit analysis no longer apply. None-the-less, for example, consider a Class AB amplifier where the tube is only cut off for 1 degree. This short cut-off would not have much affect so the analysis for Class A would apply. As the cut-off period increases the behaviour will diverge more and more from that of the Class A amplifier.

Simulations produce some interesting results:

Another way of measuring the source impedance is to observe the effect on a reflected wave entering the amplifier from the load. With a Class C amplifier, simulation reveals that the effect on the reflected wave depends on the phase of that wave with respect to the drive signal applied to the tube. As the phase of the reflected wave is changed, the reflection co-efficient experienced by the wave changes. Truly a non-linear behaviour. Intriguingly, when the conduction angle is exactly 180 degrees, this effect largely disappears, and the result is much as if the source impedance of the tube was 2 times Rp, which seems to make some sense since the tube is only conducting one-half of the time.

> One last question: Are you basing your dissatisfaction of Reflections
> from reviewing the 2nd or 3rd edition? Chapter 19 has been expanded in

> can send you a copy of the addition.

I have been reading the .pdfs at w2du.com along with correspondence and other writings in QST, QEX and newsgroups.

The expanded Chapter 19 at w2du.com offers more experimental evidence that seems to support the hypothesis that the transmitter is conjugate matched to the load after tuning,

But given, from circuit analysis, that the output impedance can not be well defined for any but a Class A amplifier, the fascinating question is why is there experimental evidence that agrees with the premise that
the output impedance of a tuned transmitter is the conjugate match of the load?

One simple example to consider which has similar behaviour is a bench power supply that also has a constant current limiter. Set such a power
supply to produce a voltage of 100V (more precisely a maximum voltage) and a current limit of 2A. Apply a variable load. Maximum power will be drawn when the load resistance is 50 ohms. Varying the resistance on either side of 50 ohms will reduce the power which might be misconstrued to suggest that the power supply has an output impedance of 50 ohms, when, in fact, it has a infinite output impedance when the load is below 50 ohms and a zero output impedance when the load is above.

I have looked for such a simple explanation in the circuits of the transmitters used in the experiments but was not able to find one.
So I am still puzzled by the observations.

After one thinks about it for awhile, one will realize that believing
in anything except physical particles is the religious faith-based
part. Can anything exist in the real world that doesn't have a
physical existence? The answer to that question is why particle
physics has become the accepted standard. Everyone who believes that
something can exist without an associated physical particle is free to
try to prove their belief but how can non-particles be measured?

You have gone to a bit higher level than I intended with my question
and
I agree with you conclusions at that level. But my question was more
```

basic.

When designing the filter for a PA, among other things, one uses the desired load to be applied to the tube and the disired load impedance to be supported and selects filter components to perform the desired transformation.

When operating the radio, the operator has meters that measure some values, some knobs that control some component values and a procedure for adjusting these knobs.

It is not at all obvious what exactly the result of performing the procedure is. Does it result in the same load being applied to the tube that was computed by the designer? There are some hints that the procedure will result in the load applied to the tube being real, but beyond that, what exactly are the circuit conditions that result?

...Keith

If the score on IQ tests ever got to the point that is currently scored
as 130 it would be, by the method that determines IQ scores, 100.

But you probably already knew that.

Since anything except a class-A amplifier is non-linear and since we
are talking about linear analysis, it seems we need to locate a point
in the system where V is a sine wave, I is a sine wave, and V/I is the
constant impedance at that point. IMO, that is the first point at
which we can use a linear math analysis and maybe that point is what
Walt is talking about. It's certainly not going to be the plate of a
class-C amplifier and it may not even be the load-line of the class-C
amplifier. There is probably some point in an otherwise non-linear
system where a linear analysis becomes possible. I think that point is
what Walt considers to be the linear source point, wherever that point
might be located.

In fact, here is my personal take on the subject. Given an antenna
system that presents 50+j0 ohms looking into 50 ohm coax, the internal
impedance of the source doesn't matter. For any voltage source,
irrespective of the source impedance, if reflected energy doesn't
reach the source, the source impedance doesn't matter (except for
efficiency). Seems to me, the highest efficiency would be achieved by
a source with zero ohms of source impedance.

Hi Keith,

By and large, Yes.

>There are some hints that
>the procedure will result in the load applied to the tube being
>real, but beyond that, what exactly are the circuit conditions
>that result?

I am a little lost on that. The load applied is the load applied (sorry for the Zen). If you mean that the load is transformed by tuning to a real R for the Plate to see, then, yes, that is operative.

However, that is not the end of it. That R is seen as the loss of a now-poorer Q for the Plate tank. This is the distinction between loaded and unloaded Q. The Plate tank Q expressed in terms of loaded Q, to be effective, is quite low in comparison to its unloaded value. This value of loaded Q is roughly between 10 and 20 where the components in isolation (unloaded) could easily achieve 10 to 30 times that.

The term "loaded" includes BOTH the plate and the applied load (whatever is presented to the antenna connection). The only time the unloaded Q of the Plate tank is at peak value is when it is sitting in isolation from the chassis, circuitry, and even mounts - which means it is not very useful in that configuration, except as a trophy. Many silver plate their tanks as trophies (because this rarely results in better operation).

Now, let's return to my statement about what Q is "effective" AND that it measures out at roughly 10 to 20. This is straight out of Terman if you need a citation. As for explanation (also found in Terman), you have to consider that the Plate tank is the gate-keeper (as well as transformer of Z) of power. If you have too high a Q, the power is not getting THROUGH the tank as it must, and necessarily it remains in the tank (as energy, albeit).

Consider further that ALL resonant circuits can be cast from series circuits to parallel circuits or parallel to series (a fact lost on some inventors of antennas). To describe the Plate tank in series terms as I do, then the plate resistance and load resistance combine in series through a simple circular path through ground. There are parallel tank designs where the resistances combine in parallel. The net result is the same insofar as Q is concerned.

Consult Terman if that is confusing. No doubt others will either more clearly cite him, or add to the confusion.

Hi Keith,

Consult Terman. That should be sufficient for both the instructor and the student to use as a benchmark design for tubes, at least. The design of the transistorized finals' deck of Ham grade HF rigs has been stable for nearly 4 decades.

Any departure from HF Ham grade equipment capable of 100W is going to lead to equivocal statements.

Hi Richard:

As I understand =3D> "output impedance of a rig be near to 50+j0" it is not a cuantitative fact except when it refers to specific study objects, obvously not all study objects (transmitters) will necessarily share those numbers.
I think a good general cuantitative assertion would be for example, "all the rig on the market gives near 50 +j0, Zout". I am not deny that experimental fact...

When I say "in my opinion" I am just not giving a formal hipothesis or theory and I quite understand technical and logical limitations of such words (for that I use them)
Certainly I am definiteley not an authoritative guy on any matter :>(

(I'm so sorry Richard, although theory of knowledge is a topic of my interest I am not in conditions of discussing about it in a (for me) foreign language :>(   )

I saw some of this topics discussed time ago in this newsgroup and it was not my intention to return to them because I know they motivated good ponderings and respectfully points of view in its moment.

PSE, with the due respect and consideration toward you an the distinguished colleagues and friends, Would you mind return to the original question? (sorry if it is not this the most polite form to ask it)

Yes, standing waves are hard to visualize, but there is indeed same-cycle interference involving forward waves and reflected waves. There is a certain delay from the source signal to the load and back that can be calculated if one chooses. The wave reflection model is closer to Maxwell's equations than is the lumped-circuit model where EM waves propagate instantaneously. Maybe the concepts presented in the following paper would help. There is no transmission line for a Tesla coil but reflection effects still exist. The lumped circuit model, to which you allude, incorrectly assumes that signals can travel at faster than the speed of light, an obvious impossibility.

http://www.ttr.com/corum/index.htm

Incidentally, this is the reason that W8JI measured a 3 ns delay through a foot-long 75m loading coil. There were same-cycle reflections existing in a near-infinite SWR situation. In such a configuration, the phase of the current doesn't change at all yet W8JI assumed the measured phase change was proportional to the delay through the coil. Nothing could be farther from the technical truth.

I BELIEVE!  Hallelujah!

Personally as an engineer i am more comfortable working with the
electro-magnetic wave representation of  radio or light waves because
i work with macroscopic objects and the waves and fields are easier to
work with.  But many physicists prefer photonic representations
because they work more with particle interactions and it is easier to
represent the interactions at that level with feynman diagrams and
similar mechanics.  but most problems can be adequately handled by
either if you apply the right methods.

I used a similar problem in my discussion entitled "A simple VSWR analysis without mirrors" at http://vk1od.net/blog/?p=1259. The article then goes on to solve a real problem (ie a practical low loss line rather than the lossless line in the first example, and in your example.

You should find them relevant.

Owen

That does not surprise me at all. I have gone through about 6 doctors in
the last two years looking for one with enough IQ to even talk
intelligently with. I now have a good one and he is from Iran and glad
to be here. The others were just pill pushers or as I am heard to say
"educated baboons". A PhD means nothing to me if there is no real
intelligence to support it. Many of these specialists have no idea about
other things and no ability to understand when I do go out of their
comfort zone. Finding real intelligence in people is a continuing
challenge for me. My IQ? Don't ask.
Cheers,
Bill Baka

Kind of what I meant. It seems that every year they are chasing
something, the latest being the 'Higgs' boson. The "Big Ring" in Europe
is a prime example by having counter rotating particles near the speed
of light smashing into each other at nearly twice the speed of light.
Sure there will be some odd particles coming from that but the life time
of these particles is sometimes measured in Nanoseconds, so they just
don't exist in the natural world.
<Sigh>

I did, but that wasn't the point I was trying to make. The bell curve would just go up to the point that people with IQ's of 100 (by today's standards) would be considered sub par. I do wish that could happen since I can't deal with even average people. Sometimes I accidentally use a big word or describe in detail something they don't know and I get labeled either a show off or just plain smart ass. It is totally unintentional but is happens.

Hi Cecil. thank you very much for your answer. (I am a "fan" of your rationale and very practical multiband open wire antenna feeding and I do not know why it is no so popular as G5RV in my country).

....

I know a model is necessary false by definition because is only a model (an approximation to the hipothetical "real thing"), but I do not imagine what is the tranmission line in the source-load combination of my idealized model circuit example. I am not capable to judge validity of idealized circuit theory in general to this example, neither. Please, could you tell me which would be the transmission line Zo in my resistive divider example?

Anyway, my question is about validity of the assertion that reflected wave -in that example- IS ABSORBED by the pad. According to my simple calculations this hipothesis, as I see it, it does not coincide with my early learnings.

For example, with a 2 V generator with Zs=3D1 ohm, Zc=3D4 ohms and Zo=3D1 ohm, Pc is 0.64 W. Then Pf =3D1 W (as Owen says in his article), Pr=3D0.36 W. Rendering Ef=3D1 V, and Vf=3D0.6V. Summing both in phase gives 1,6 V on the line-in point (same as on load point).
These are the same power and voltages values that simple resistive divider predicts. The system fulfills the Kirchoff law and all power (as we learn in circuits theory) it flows from source to load.
In the example I suggest a half wave transmission line loaded with 4 ohms it is at practical effects indistinguishable from a 4 ohms resistive load directly connected to generator. What would be the reflected power that would be dissipating in Zs (or the pad)?

This is not opposed to the conjugate mirror principle explained, neither other propositions given in the cited article. IMHO reflected power never "returns into" generators when they are active (and in steady state); reflected power it is re-reflected in conjugated match, and vectorially composed to render a load impedance to the generator when this is directly connected to the line (when there is not any matching devices inserted).
I do not suggesting that reflected power is "virtual" or any similar thing, of course if we insert a circulator to separate both powers, generator now would see 1 ohm load, could develope 1 W incident, 0 W reflected (Pn=3D1W) on circulator input, 0.36 W would be outputting on the other port to render 0.64 W (Pn) to the load with 1 W Pf and 0,36 W Pr again.

If I am in error please give me your explanations.

I'm going to be putting an NMO-mount dual band (144 and 440 MHz) antenna in a plastic vehicle roof.

I plan on making a counterpoise using 3 inch wide (or so) adhesive-backed metal (hvac) tape. I can do an overlapping run of close to 6 inches wide.

Question for the crowd -- any benefit/detriment for making this counterpoise as long as possible, or should I stick to odd multiples of a quarter length (at 2 meters)?

There's more room "behind" the mount point than in front of it, so I could have a quarter wave section in front of the NMO, and a 3/4 wave section behind.

I can also do a cross member, but that would be pretty much limited to
a quarter wavelength per side.

Opinions?

Good luck trying to get a good electrical connection to that stuff..
I'd probably just stick to odd multiples..
You could use wires also.. In fact, just two wires 180 degrees
apart will give you a fairly omnidirectional pattern with minimal
fuss. Easier to solder too also..
You could probably use the longer radials for 70cm, but you
could also add shorter radials for that band if needed.
BTW, another thing about that tape.. After a few months of
summer heat pounding the roof, the glue will become useless and
it will fall down on you. :/

I'm probably in that range myself, since I can knock off a 150 while
talking to my boss, and in the multitasking mode. I considered joining
Mensa but their standards are too low for me. Lately I have just learned
to not speak out on anything since there are so many people who do not
want to hear, or learn anything. My wife is a prime example, couch
potato, thinks American Idol is a MUST see, and well,.... you get my
drift. I hate having to dumb down for the masses.
Cheers, see you in the stratosphere.

Cecil Moore, W5DXP wrote:
"Seems to me, the highest efficiency would be achieved by a source with zero source impedance."

Me too, but zero source impedance does not match the load as required for maximum power transfer. The best combination is then a source impedance matching the load and which is also pracrically lossless. The Class C amplifier does this by acting as a switch which is infinite in impedance when open during a large part of the RF cycle and a near short circuit to a low impedance (near zero Z) D.C. power source for the short part of the RF cycle it is switched on. It is the time averaged impedance which counts. Is this linear? No way, but the tank circuit is able to remove the harmonics and turn current pulses into a low distortion sine wave. Efficiency? Terman says on page 450 of his 1955 opus that Class C eddiciency is typically 60% to 80%. Compare that with 50% efficiency in a Class A amplifier.

Best regards, Richard Harrison, KB5WZI

Well Owen...I have just read your article =A1and you have put me definitively in a problem! :>)
I was never happened to question the Walter's work, I made effort in learning it being a young student. Now you have put me in a corner and I will must meditate hard about the issue (with your help, certainly).

In principle I take a risk to think that somehow it is necessary to solve "what to do with the reflected traveling wave" because the model seems to demand "come off of her" somehow that it doesn't return into the generator, and an explanatory model (and IMHO appropriate) of making it is to postulate its re-reflection to be consistent with it.

In conventional theory of circuits we simply apply the second law of Kirchoff because we do not have traveling waves and we accept that the energy can only flow from the generator toward the load (supposing a circuit without reactances), there is not anything to come off (in spanish =3D> deshacerse, desprenderse) :>)

I am happened to think that your article combine concepts of both models, those of basic circuit theory (without traveling waves) and those of the traveling waves -same as my simple example of course- with the difference that in mine one I only wanted to point that the reflected power is not "absorbed" by the pad, and yours is critic of conjugate mirror model and other postulations.

I think the mixture or combination of models -maybe- it would not be "elegant" or consistent although it can arrive to the same numerical results, but I don not dare to advance more than that in my speculations :>)

Hi Miguel,

I presume by "original question" you mean:
>On Mon, 24 May 2010 13:06:19 -0700 (PDT), lu6etj <lu6etj@gmail.com> wrote:
>
>>�Absorb the reflected power or amortiguate the effects of variyng load
>>impedance?

The answer is YES.

Now, if you mean by absorb that all absorbtion results in heat, then
the answer is NO.

If you mean by absorb that all energy is combined in a load, then the
answer is YES.

The difference between YES and NO is the PHASE differences of the two
energies that are combined.

Miguel,

My explanation uses standard linear circuit theory, and the RLGC model of a transmission line (captured in the Telegrapher's equation). It is a frequency domain model, and it is complete and consistent.

One of the things that creates confusion in some peoples minds is that they want one foot in the frequency domain (where you can talk about concepts like reactance, complex impedance, VSWR) and simultaneously, one in the time domain taking about re-re-reflected waves.

You can work in either domain, and you can transform between domains, but trying to be in both at the same time creates problems.

BTW, if you think the problem is challenging to solve in the frequency domain, don't even think about trying to solve it in the time domain.

So, do not worry about re-reflection, it is dealt with as you have discovered by the steady state solution when you load the source with the (steady state) impedance seen looking into the line. The resolution of the wave component voltages and currents with KVL and KCL at the circuit nodes gives the steady state solution. The Telegrapher's equation gives you the amplitude and phase relationship of the wave components for the transmission line, not just for fictitious lossless lines, but for practical lines as the example demonstrates.

A steady state frequency domain analysis is quite adequate for most ham problems. You don't see it spelled out as such, but that is how the ham handbooks describe and solve problems.

As far as the myths about PAs destroyed by absorbing reflected power,
see "Does SWR damage HF ham transmitters?" at
http://vk1od.net/blog/?p=1081 .

Owen

Hi Richard and Owen

To Richard: What I mean is irrelevant :>) relevant is what Walt
wanted to say in this sentence: "Because of the absorption of the
pad, the generator sees a nearly perfect match for all load conditions
and all reflected power is lost "
Pllease, tell me what in english means "all reflected power is lost"?
I understood (or translate or interpret) that reflected power is
dissipated in the pad: Is it a bad translation/interpretation?

To Owen: Sincerely thanks for your reasons. You can be sure I will
take note about your explanation an take some time tu analize it, but
I am not sure about to arrive at at the right conclusion because what
I read in this newsgroup is a long-standing discussion here.

Miguel

Another bit of reading that might help shed light on the matter is
http://eznec.com/misc/Food_for_thought.pdf, written eight years ago
during one of the many times the subject has come up before on this
newsgroup.

The chart and discussion in the "Forward and reverse power" section show
that the concept of "reflected power" being absorbed in or dissipated by
the source is incorrect. I find the concept of traveling waves of
average power to be misleading at best, and analyses using this concept
lead to impossible conclusions like the supposed absorption of power in
the source resistance.

Yes, it is a recurrent discussion item. No doubt someone will be along shortly to add some confusion to the pot.

A parting thought, do not confuse the process of establishment of steady state with steady state. The only reason that a steady state solution is valid, is that the system spends most of its time in steady state, or substantially so. If the solution needs to focus mainly on establishment of steady state (in other words, the system never substantially settles), then you should be doing a time domain solution, and VSWR, reactance, complex impedance are not a time domain concepts.

If you need to convince yourself, do a hand workup of five of ten transits with a sinusoidal excitation. See that is does converge, and quickly, and that at the load end, the reflected wave relative to the forward wave is a fixed ratio (and hence VSWR) that depends ONLY on Zo and Zl, there is NO influence by the source or any perceived source reflection on the steady state. There are some animations of this on the net, but they seem to confuse people more than enlighten them.

Owen

In optics the light is in form of packets (oscillations for short time and
next brake - of course there are many sources).

>how could he see it since the equipment was set up to radiate into a
>detector. It may not be in our lifetimes that the true nature of light is
>discovered.

Why?
If we can produce the artificial light (LEDs, laser) and we know that radio
waves are the same then we know all.
Radio waves are very convinient to analise.
They are the longitudinal electric waves which propagate in the electron
see.
It is very old theory. The only trouble was with the polarization. But now
radio people know that the dipole is polarised. In nature all light sources
are in form of dipoles.

Well, for the purposes of application of linear circuit theory, linearity means that V is linearly related to I, or at least dV/dI over the operating range is substantially constant.

If the circuit is not linear in those terms, then you cannot form a valid Thevenin equivalent circuit, and discussion of the Thevenin equivalent series source impedance is a nonsense... it cannot be used.

Natural packets (photons) have probably the same length so the above is
obvious.

In one wavelength but still in packets.

But now are the fantastic lasers with the infinity "packet". Exactly like
radio waves:
""As the electrons are undergoing acceleration they radiate electromagnetic
energy in their flight direction, and as they interact with the light
already emitted, photons along its line are emitted in phase, resulting in a
"laser-like" monocromatic and coherent beam. The mirrors show in the sketch
below are superfluous, as all the light is emitted in one direction anyway."

> Enjoy!

One thing: the MTM loop antenna doesn't need a connection to the AM
radio. That web-page, if I read it correctly, said you only needed to
put the radio next to the loop antenna.

>
> Since anything except a class-A amplifier is non-linear and since we are talking about linear analysis, it seems we need to locate a point in the system where V is a sine wave, I is a sine wave, and V/I is the constant impedance at that point. IMO, that is the first point at which we can use a linear math analysis and maybe that point is what Walt is talking about. It's certainly not going to be the plate of a class-C amplifier and it may not even be the load-line of the class-C amplifier. There is probably some point in an otherwise non-linear system where a linear analysis becomes possible. I think that point is what Walt considers to be the linear source point, wherever that point might be located.

Recalling that if a conjugate match is achieved at one ponit in a system
it is achieved at all points....

It does not seem possible for a system to be non-linear at one end and turn in to a linear system at some other point.

> In fact, here is my personal take on the subject. Given an antenna system that presents 50+j0 ohms looking into 50 ohm coax, the internal impedance of the source doesn't matter. For any voltage source, irrespective of the source impedance, if reflected energy doesn't reach the source, the source impedance doesn't matter (except for efficiency). Seems to me, the highest efficiency would be achieved by a source with zero ohms of source impedance.

True, if the source impedance originates in dissipative components and it is a voltage source. For a current source, infinite impedance offers
the best efficiency.

It seems to me that much too much is made of 'maximum power transfer'
in
the RF world. In the world of 50 and 60 Hz, where significantly more
energy is moved, 'maximum power transfer' is never mentioned.
Efficiency
is much more of interest.

For the most part, 'maximum power transfer' is just an interesting
```

ideosyncracy of linear circuit theory.

sorry, last reply have real antennas to work on today.  it was in
between them that the aether was pretty well shot down, you like
wikipedia, go read http://en.wikipedia.org/wiki/Michelson%E2%80%93Morley_ex=
periment
and think some more.  dirac was trying to resurrect the aether, that
doesn't make him any more correct than you or art... even the best
thinkers have some bad side trips, the best of them know when to admit
they are on a dead end.

I have one I made years ago that is similar, so I can describe it for you.

Materials needed - about 32m of wire, light plywood (I used scrap), 365pf (or anything close) capacitor, connector of choice.

My box is made with 127cm by 13cm plywood pieces joined as an X, which will give you a 90cm square box. The dimensions are not very critical. Drill 10 evenly spaced holes near the end of each piece. Thread the wire through the holes until 10 turns are in place. You will bring the 2 tails of wire in to a point near the center of the X where you have mounted the tuning capacitor. Solder the tails to the capacitor. Drill 2 holes in the end of each piece just inside of the 10 turn loop for the pickup loop and thread a 2 turn loop into place. Run those tails to a point near the center of the X where you have mounted your connector of choice. Solder to connector.

Connect your AMBCB radio and tune the capacitor for max signal strength. Enjoy!

Vary size of box, number of turns in loop, and value of the capacitor for other bands.

tom

When I was in college, I observed a stream of electrons emitting a
glow that traveled at the speed of light to my eyes which evolved to
detect photons, not electrons. Since photons can do that, why is there
a need to introduce the concept of invisible, undetectable, massless,
virtual electrons in free space? What is the electron density of free
space?

An "infinitesimal," center-fed, linear dipole has a peak directivity/
gain of 1.5, or 1.76 dBi.  Getting any r-f energy to flow on it takes
some real heroics,  though.

Havent seen one of those in years. Made one when I was a kid in High
School. It was my project in woodworking and physics class.

>sorry, last reply have real antennas to work on today. it was in
between them that the aether was pretty well shot down, you like
wikipedia, go read
http://en.wikipedia.org/wiki/Michelson%E2%80%93Morley_experiment
and think some more.

The aether of Lorentz was shot down. Michelson in his famous experiments in
1887 and 1925 (with Gale) proved that the aether rotate with the Sun but do
not rotate with the Earth. Such model of the aether was made by Stokes, the
chamption of the aether.

Lorentz aether was motionless. You know that the Sun rotate. Why the plasma
do not?

The evidences of that are collected by A. G. Kelly:
http://www.worldnpa.org/pdf/ebooks/Kelly%20-
%20New%20Theory%20of%20the%20Behavior%20of%20Light.pdf

> dirac was trying to resurrect the aether, that
doesn't make him any more correct than you or art... even the best
thinkers have some bad side trips, the best of them know when to admit
they are on a dead end.

Maxwell was full of doubts.

The aether is shot down from teaching program. The plasma is included.
If somebody do not like the "aether waves" he can use the "plasma waves" or
something else..

I don't think a pursuit of destroying Ohms laws is going to prove anything.Preservation of time is a must with respect to accelleration of charge. Would it not be better to operate within Ohms law with a dipole of "near" zero resistance and then apply a time varying current from one resonant frequency to another.You then obtain a trend of the change in volume of radiation. I suspect that the maximum radiation volume could be reached prior to zero impedance dependent on the particle transfer and replacement time. Working within existing laws and environments narrows the variables and narrows the scope of the eventual debate around the findings. The subject is determination of maximum volume of radiation which has nothing to do with "gain" using existing definitions.I see nothing unreasonable in using a computer program to extract data provided by changes of applied frequency.

Got a station antenna setup.   I have twinlead up to 140' per side dipole. I have a desk, facing a wall.   Window over to the right.   Right now, I have coax coming out of my antnenna tuner, going outside, through the window, to a setup to feed balanced line.

For years, I've thought about what would happen if I brought balanced line into the house.

I've got a metal filing cabinet between window and ham shack.   I'd have about 5' of line from my tuner, going around the cabinet, and finally getting to the window.

How much performance degradation would this give me to do it in spite of the metal cabinet?   I know for years they say: don't let twinlead come near metal objects.   This would be doing that.   Wonder how much degradation I'd suffer if I did that?

max volume equals 0dbi gain, by definition.  not very practical and
hard to achieve in a real antenna.  for most 'normal' applications we
have some kind of preferred direction so directional antennas from
simple dipoles to big dishes are more useful.

ah yes, that ugly little thing called mass... because electrons have mass they can not travel at c, therefore they can not be the carriers of electromagnetic radiation. also, it is well known that photons have no rest mass and no charge, both of which disqualify the electron also. you should really talk to art, he is much closer with his magical levitating diamagnetic neutrino.

Hi Mister S
Thank you for supplying reference for the article in the phylisophical
journal. Most of it is beyond my interlect
but a quick review show that the tenents of his explanation
are based first on the requirement of equilibrium
That particles is the center of discussion
That vortices are present to provide a displacement force
And the connection between electrostatic and light
functions. Nowhere do I see reference to Gauss law of statics and the
progression to a dynamic field which makes
his paper some what astounding for him to come up with this paper
without these clues that have been hidden for so long. I intend to get
a print out of all four portions of this paper in the hope I can
cherry pick some portions that I can understand from the paper. As
always one of the most important things are the responses from his
peers which
usually are accompanied by science analysis rather than relyinging on
base intuitions without supporting facts from the ham community.
Thanks again
Art

Oh my. ! The above is the silliest thing I have heard in a long while,
but I am very glad you presented it
as an example of your private analysis. It shows that tho free speech
is viable what is contained in the enunciation is not necessarily
anything other than trash. And I just love that position of yours
"it is 'well known' that photons have no rest mass and no charge".
Don't you have to repeat that a 1000 times before it can be considered
true?

As they say, "Suck it and see" (especially if it's easy to try).
Keep the feeder as far as possible from the filing cabinet (rotating it,
if you can). [No, not the filing cabinet.]

If you don't try it yourself, and report back here what your findings
are, in six months from now, this thread will still be going strong.

Probably none. Performance might actually increase slightly if the
coax to twin lead connection is lossy. I'm not a fan of running coax
to
twin lead. If I use a tuner, I run twin lead or ladder line the whole
route.
The "twin lead near metal" issues are often overblown.
Like Ian says, try it and see what happens.

$137.50... Dang.. Maybe I should start selling loops.. They sure
seem to be proud of them when they apply the price tag.
This is my version of the same appx thing, except using a
simple PVC frame. Can be built for chump change if you have
an old BC variable laying around. If not , the caps can be
bought on the web.. I scrounge mine out of old analog stereo
receivers, radios, etc..

So much so that neither of you noticed that the article is scanned and
ocr'ed from somewhere resulting in none of the equations being
faithfully represented. For most I would expect this to result in
difficulty understanding the principles presented.

Art, is there any chance your high observed gain is because antenna has
very low impedance that the currents may be overly elevated from the
voltage source used in your model?

Low impedance leading to higher current leading to higher fields being
generated leading to higher perceived gain.

If you can choose antenna parameters that result in negative resistance,
does this really mean your model is working properly under the
conditions you are using?

Art,

Please enlighten us.

What is the mass of a proton at rest?

Please quantify the charge of a photon.

much is beyond your intellect...  however you should note that gauss's
law wasn't published until about 6 years after that article, so it
would be surprising if it was referenced.  that article is also well
before maxwell had published his works that contain his completed set
of equations describing electromagnetic fields... so it is not
surprising that some of what is in there was undoubtedly incorrect
guesses and suppositions based on earlier observations.

For my 80 meter dipole, I have 92 feet of twinlead running around the
roof, and through the window, to my tuner -- it passes a few metal
pieces here and there, and I can't see any problems. I'd say give it a
try -- it's the only way to find out.

I use one of the MFJ window feedthrough panels to get the twinlead
indoors -- they work very nicely.

I have not printed the article as yet and I admit that I had not noted
the earlier publication date. I thought the publication was just one
year old.
I believe it to be interesting enough to get a print out but it will
be difficult to get a full list of comments
which usually as interesting as the article itself.

Joe, I have not seen a description of a photon and I believe a sample
is yet to be maintained.
Possibly the accelleration of a neutrinos and the resulting collision
will separated the charge from the neutron so one can see if it is
accompanied by a morsel of mass. I say that because as the neutrinos
is the smallest mass known which leads to the maximum speed of light.
Thus collision should not be able to separate the neutrino alone and
only separate attatchments.
But my readings on the subject is some what limited.

Yeah, I was thinking how fast I could mass produce say a dozen at a
time.

Jimmie

Certainly if you consider I sq R and the removal of losses made by
penetrations into the metal . But there are other considerations such
as the swamping of diamagnetic action in air after near removal from
the metal itself because the change in eddies strength changes every
thing.
I cannot explain the mechanics of what is actually happening and can
only be guided by what the programs infer. Intimate discussion of the
above is more than welcome. Especially the realization of maximum
radiation determined by the time needed for the replacement of the
ejected particle which probably occurrs before minimum impedance is
reached. I cannot imagine the addition of zero or negative values in
the equation since only the contents of the boundary is relevent in
accountability for all forces as I see it based on
Newtons laws. Joe your comment are the first review that is willing to
discuss the merits of my work and I sure welcome it so that closure
can be reached

Now Cecil you never did observe actual electrons let alone a stream !

> glow that traveled at the speed of light to my

Now Cecil you have no way of knowing what the speed was or even the
timing function required by the eyeball.

eyes which evolved to
> detect photons, not electrons.

```
Where is that stated in print? It has to be in print to be true right?
Cant you reference an eyeball to function the same as a Faraday cage
because a brain requires an electrical circuit?

 Since photons can do that,
Does the eyeball have counters to count the dropping photons or what.

 why is there
> a need to introduce the concept of invisible, undetectable, massless,

I have no idea what physisist presented to show that there was a need

 What is the electron density of free
> space?

Gulp!
Space is homogenous in electron content? If so
how can a solar stream exist?

Cecil, as a side note I posted about coils radiating
since you were responsible for record length threads as to whether and
how they radiate. I lost track how all that fell out after the first
year of the record postings. Did you beat out the detractors?

```

Hello Sven,

Glad you received your copy today. To pique your interest in tx output impedance, Chapter 19 will do that for you, especially Sec 19.14 on Page 19.22. This section describes in detail, in fourteen steps, how the output Z is measured.

I've seen a lot of discussion on this subject, and most of it shows that many who discuss it don't have a clue to the correct answer. Which is why I have made many measurements of the output Z to determine the truth.

The output Z is determined principally by the proper adjustment of the tank circuit with respect to the load. I'm talking now only about tube amps with pi-network tank circuit coupling the amp tube to the load. I cannot comment on solid-state rigs, or those that have no tuning adjustments.

There are those who believe that the output Z = 50 + j0, and there are those who believe the Z is much higher. Here's what really happens. With any practical grid drive, load and tune the amp into a 50 + j0 dummy load to deliver all the available power. In this case the output Z of the amp will be 50 + j0 ohms.

Now add 50 ohms of inductive reactance to the same dummy load. The result is now a load impedance of 50 + j50 ohms. Now reload and retune the pi-network to again deliver all the available power into the new complex-impedance load. The new output Z? 50 - j50 ohms, the conjugate of the complex load impedance. In other words, to determine the output Z of the amp, simply load it into an impedance of known value such that all the available power is delivered at a reasonable drive level. The output Z is then the conjugate of the load impedance.

You say you want proof of this simplistic procedure? Fine. It's all right there in the fourteen steps in Sec 19.14 that describe the entire measurement procedure. I'm sure you'll find the procedure enlightening.

Walt, W2DU

Mike, apparently one can't divulge one's email address on this NG.
However, we'll fool 'em--the word preceding @ is walt. So there, too.

Walt

I'll be using 100 watts SSB/CW, and have about 75' of twinlead up to antnenna feedpoint.

You've got me going to do the "system degradation question":   I'll run twinlead to the shack, in spite of the file cabinet.

Now, yes--I can do just fine manually changing my antenna from ladderline fed to putting it on 160 by jumping both ends together and letting it work against ground.   Long counterpoise in place. Then, putting it back as twinlead dipole on 80m up.

What's the new question?   I normally would go from 160m up through 15m. If I just used the jump both ends together and feed long wire, which ant will be better?

Basically, it's whether a long hat vertical would be as good as using my twinlead as dipole on bands including 80m and up.

I can certainly keep the antenna twinlead fed dipole, no problem.   Just curious.

Can I rain on your parade? Light is just super high frequency RF. There
is no such thing as a photon but scientists still use that to explain
things in human terms for the unknowing masses. The best way I can
describe a photon is that it is one wavelength of light at any given
wavelength or frequency if you will. If a star or even our own sun gave
off photons at the rate of burn then it would very soon be an ex-star.
There are very few people who can think at the needed level for this
kind of thing, so let the argument continue. Really silly thinking that
there are red photons, green, yellow, etc.

Exactly. Imagine a tornado which is a macro scale version of the vortice seen as a displacement current as a series of capacitors along side the current flow within which there is circular flow. This is no different to the laminar flow in a firemans hose. Put projections inside the hose and you can get multiple vortices because of the lamina friction.You probably have heard of "curl" with respect to antennas and yes that is described with respect to vortices. So it is not so far out to see a tornado as a cloud enclosed by neutrons in terms of a skin tension. This all goes back to the release of a small particle from the boundary enclosing the big band where rotation is applied to same via the levered fracture in the boundary as it momentarily loses equilibrium. For the above tornadoes are seen as the swirling action between capacitor plates comprised of ground and the upper layers. The capacitor plates perform the same action as a "idler" wheel so that ejected rotations of particles have

the same spin.
Review vortices if only to get a physical idea how the term "curl" fits in with respect to lamina flow which you can then expand to magnetic lines or field of a magnet for a better understanding of transitions. Everything on Earth can be described by the two vectors created at the big bang down to the two vectors of gravity and rotation where rotary flow introduces lamina slip and the adherence to Newtons laws including his equations for acceleration. All the above is thoroughly seen under boundary laws which are centuries old, when static fields are transformed into a dynamic field. Nothing new, no new laws or equations but just a different method of connecting the known dots determined by past physics to produce a closed circuit similar to the tank circuit in parallel

On most bands it will operate the best fed normally as a dipole.

>Hi Mister S
Thank you for supplying reference for the article in the phylisophical
journal. Most of it is beyond my intellect

Do not worry. Maxwell is an excellent writter and his English also.
Everything is wrote in English and next in Math. The math is to calculate.
We do not calculate enything.

>but a quick review show that the tenents of his explanation
are based first on the requirement of equilibrium
That particles is the center of discussion
That vortices are present to provide a displacement force
And the connection between electrostatic and light
functions. Nowhere do I see reference to Gauss law of statics and the
progression to a dynamic field

Maxwell described the rotational oscillations.
Gauss dynamic field is simply the longitudinal oscillations (like sound).

>which makes
his paper some what astounding for him to come up with this paper
without these clues that have been hidden for so long. I intend to get
a print out of all four portions of this paper in the hope I can
cherry pick some portions that I can understand from the paper. As
always one of the most important things are the responses from his
peers which
usually are accompanied by science analysis rather than relyinging on
base intuitions without supporting facts from the ham community.

Thanks again
Art

Nice reading.

It is math for it (Doulong). If a cristal is kicked it radiate diffrent
frequences. But not all and for a limited time.
Higher frequency bigger energy. But such packets are longer than one
wavelengh. It is a coherency of radiation.

Some substances emitt only one or only a few wavelengh. Sodium emits yellow.
(Sodium emitts yellow packets?).

Cecil does not suggest that. What can means the level and fluctuations. Now
everybody measure it:

While the analysis of transmitter output impedance in Reflections is
flawed,
experiments (claimed to be repeatable) described in Reflections appear
to
support the conclusions of the flawed analysis.
```

It would be highly valuable if the results of these experiments could be explained in a manner that aligns with established understandings.

Such an explanation might start by describing the circuit conditions that result from following the manufacturer=92s tuning procedures. After all, these usually depend on measuring currents and voltages so are only indirectly related to power. Perhaps the resulting conditions are not as they are usually assumed to be.

Try as I might, I have not been able to derive a mechanism to explain the observations in Reflections. But the explanations offered in Reflections require large chunks of linear circuit theory to be discarded, so this does not seem to be an appropriate path.

...Keith

On an old tube transmitter, e.g. a Globe Scout, when the manufacturer specifed a particular grid current and a particular plate current, does that imply a particular single resistive load line for the final tube? Why were those particular grid and load currents chosen? Maximum efficiency? Tube life? Minimum distortion?

I did a Yahoo search for, "eye detection of photons", and got 705,007
hits. Here's one of them from the Kansas State University Physics
Dept.

http://web.phys.ksu.edu/vqmorig/tutorials/online/wave_part/Single%20Photons=
.html

"It has been demonstrated that light-sensitive cells in our eye (rod
cells) are able to detect single photons."

Excellent questions. I have often wondered if the manufacturer's
tuning
procedures had anything to do with maximizing output power transfer,
or
were they, in fact, optimizing some other aspect.

Keith, would you please elaborate on why you believe my analysis of transmitter output impedance is flawed? And what is the basis for your belief that my explanations in Reflections require large chunks of linear circuit theory to be discarded. Could it be because you consider the source resistance in the transmitter to be dissipative, as in the classical generator? If so, you must be made to realize that the source resistance of the transmitter is non-dissipative, which is the reason that its efficiency can exceed 50%.

Or are you considering the output characteristic of the transmitter to be non-linear? This is not the case, because the effect of energy storage in the tank circuit isolates the non-linear input from the output circuit, which is linear as evidenced by the almost perfect sine wave appearing at the output of the tank.

One last question: Are you basing your dissatisfaction of Reflections from reviewing the 2nd or 3rd edition? Chapter 19 has been expanded in the 3rd edition, in which I presented additional proof of my position on the subject that you should be aware of. If you haven't yet seen the addition that appears in the 3rd ed, please let me know so that I can send you a copy of the addition. Also include your email address so I can send it.

Keith, you are the only person I know of who appears to have found flaws in my presentation on this subject. Which is why I'm anxious to know exactly why you believe my presentation is flawed.

Walt Maxwell, W2DU

What is your theory of exactly what is incident upon my retina that is
traversing the distance from the electron stream to my eyes at the
speed of light?

The longitudinal electric waves (electrons oscillations).
The sound waves are also longitudinal (air partcles oscillations).

The theory is from XIX century. It is not mine.

cells) are able to detect single photons."

But remember what Bill wrote: "There
is no such thing as a photon but scientists still use that to explain
things in human terms for the unknowing masses. The best way I can
describe a photon is that it is one wavelength of light at any given
wavelength or frequency if you will."

For light the photon has about 200 wavelength.
Radio wave "photon" is as long as transmitter works.

Dick,

Any decent balun built into a center connector is OK. W2AU or Radio Works
are examples. You can even use the budwing center connector plus a separate

balun.

That explains why UV is harmful, higher frequency, while IR at longer
wavelengths is just heat.

Agreed.
That is why LED's emit at only one wave length. It just depends on which
elements are in the LED formula.
Bill

```

Hello to All
Yesterday I took down a small HF beam antenna,for lady whose husband just passed away.
He had bought it last year brand new.At 1st I thought it was a Butternut Butterfly beam,but its not.
The reflector is a elongated triangle with wire around the perimeter of it and has clear tubes for support of the triangle that go into Aluminum tubes of the support structure,in the middle of the triangle is a plastic hub that it all ties into and mounts to the boom.The boom look like aprox 10' long,the driven element has a matching network of some kind that is in a gray 4x4 box,and at each end of the driven element it has a hub with about 8 rods on it,the director is almost the same as the driven but is not split in middle and has the same hub and rods at the ends of it as the driven element.
I hope I explained ok the best that I could do
Any input would be great
Thanks all and have a nice summer
Howard

 If you are correct, the feedpoint impedance of a 1/2WL standing-wave
dipole should change from 75 ohms to around 600 ohms (traveling wave
antenna) when installed in free space. Does NASA know that resonant
standing-wave antennas, like 1/2WL dipoles, will not work in free
space because of all those free electrons in free space?

There is a clue in there. Use of the terms does not indicate correctness, just useage.

While for any given case of Art's antennas, whether the theory, or the actual described antennas - I just don't understand the theory, and the antennas, which are usually explainable by other, less abstruse and more well known methods.

In at least one case, the coil on the end of a mast 160 meter antenna, well, it's a tuned circuit on the end of a stick. No doubt it works in similar fashion to the other antennas of the same ilk, relying on feed line radiation. Nothing new, and no need for new theory in the case that the old one describes it well.

In any event, extraordinary claims require extraordinary proof, and Art is not willing to provide, we are supposed to believe him based on it being him.

Wrong-o-freaking-rama! Just about anything can be explained in some fashion to just about anyone, and the onus is on the one trying to explain. I've never had a problem understanding anything else the experts have offered. That brings us back to my first sentence.

An ordinary proof would be more than adequate. It is the
"extraordinary" proof (aka radiating particles on diamagnetic rods
enclosed in the equilibrium of a faraday shield to induce the
Luxembourg effect) that is probably the surest indicator of deception.

Sal, KD6VKW wrote:
"Wharever the reason, performance was worse, not better."

Sal, thank you for your U.S. Navy service.

My experience with diversity was different. At Radio Free Europe we relayed broadcast programs by HF radio before communications satellites existed.

We used Hammarlund SP-600 receivers in triple diversity. We found most other receivers deficient. Our receiving sites were remote ffrom our transmitting sites to avoid interference. We used UHF for short haul relay.

For HF triple diversity each of the SP-600s was connected via an isolation amplifier with a separate rhombic antenna aimed at its transmitter. Outputs of the three receivers was fed into a Crosby or Pioneer combiner which elected the best signal and rejected the other two.

The horizontal rhombics each required four towers because they were laterally spaced about ten wavelengths apart for space diversity at one of the lower allocated frequencies. We, at times resorted to frequency diversity too.

The receiver operator listened to both of the sidebands of each transmitted frequemncy and selected the better of the two for reception manually.

By selecting the cleanest frequencies and sidebands and using the output combiners to select the instantaneously best of three signals, broadcast quality programs usually prevailed.

Best regards, Richard Harrison, KB5WZI

I have something like this:
http://perg.phys.ksu.edu:80/vqmorig/programs/java/makewave/Slit/vq_mws.htm

See also 1864 in:
http://online.physics.uiuc.edu/courses/phys435/spring10/Lecture_Notes/A_Brief_History_of_Electromagnetism.pdf

Transversal wves have no sense. The equations are usefull for teaching the math.

dipole should change from 75 ohms to around 600 ohms (traveling wave
antenna) when installed in free space. Does NASA know that resonant
standing-wave antennas, like 1/2WL dipoles, will not work in free
space because of all those free electrons in free space?

Alternate electric field from the ends of the dipole kicks the electrons in

the space and they oscillate (longitudinal electric waves).

I suppose you are right there Richard. Its just that we don't often get the chance to use extraordinary twice in one sentence very often, I just got carried away.

> It is the
> "extraordinary" proof (aka radiating particles on diamagnetic rods

I was thinking his explanations might involve the Stockholm effect.

right, read this carefully from that 1864 note: 'the requirements of
his mechanical model keep him from finding the correct boundary
conditions, so he never does this calculation'. This is just one of
the basic shortcomings of using a mechanical analogy, you can not
satisfy the electric and magnetic field boundary conditions that the
final version of his equations handle properly. while some basic
effects like the interference patterns can be duplicated for both
longitudinal and transverse waves, they are not interchangeable in all
cases and trying to do so will only lead to absurd things like
electrons jumping off antennas or the need for an aether to transmit
em waves.

How much I^2*R loss is there in the plasma conductors of free space?
How far into space does the electron plasma effect extend? If
electrons can flow from a cold aluminum element in a vacuum, why does
a vacuum tube need a special heated cathode?

```

I built a 2m J-Pole from 1/2 inch copper tubing.
I am going to put a page about it on my website.(HTTP://ai8o.yemiola.net
)
The webpage will have a short history of Zepps and their evolution
into J-poles.
I took pictures during construction showing how it was constructed,
and will post them also.
 Does anyone have a current/voltage plot of a J-Pole that they would
be willing to share, so I can post it on My J-Pole webpage?
I have found several diagrams of J-Pole dimensions, (like the one in
the ARRL Antenna Book),but I have not found any Current /voltage plots
for a vertical J-Pole.

his mechanical model keep him from finding the correct boundary
conditions, so he never does this calculation'.

> This is just one of
the basic shortcomings of using a mechanical analogy, you can not
satisfy the electric and magnetic field boundary conditions that the
final version of his equations handle properly.

In science area are scientists and teachers.
All scientists know that electricity, magnetism and gravity are the same.
Teachers know that the three must be taught seperately. Are you a student?

> while some basic
effects like the interference patterns can be duplicated for both
longitudinal and transverse waves, they are not interchangeable in all
cases and trying to do so will only lead to absurd things like
electrons jumping off antennas or the need for an aether to transmit
em waves.

Maxwell's model is for the aether. But with the two substances: magnetism
and electricity.

Your antennas have the blunt tips to prevent the "jumping off ".
The alternate voltage in the ends create the oscilation of electrons in
neighbourhood .

Electrons in space are detected. So they are the aether.
Do not you hear on Dirac electron see?

Oscillations are not travelling. Loss are only when something travel between
obstacles.

>How far into space does the electron plasma effect extend?

As far as light do.

>If electrons can flow from a cold aluminum element in a vacuum, why does
a vacuum tube need a special heated cathode?

Also exists the field emission. But it is harmfull for antennas if it is in
form of sparks.
The high voltage kicks the electrons in the neighbourhood.
Probably the electrons flow (and come back - but it is not symetrical)) from
a cold aluminum element. Anenna radiate if VSWR is low. It means that not
all come back.

The Clemens match is a variant of the gamma match that gets round that
problem. I tried them on 6m and 4m.

Http://www.qsl.net/yt1vp/THE%20CLEMENS%20MATCH.htm

You need to watch the losses in the coax dielectric. I vaporised  UR67
and had to go to PTFE.

no, i am not a student, i am an engineer by training and scientist by
title. where in maxwell's equations is there an aether?

not all antennas have blunt tips, and electron's don't just 'jump off'
an antenna.

no, just because there are electrons in space doesn't make that an
aether. there are electrons flowing in vacuum tubes, that is a
current, not an aether to carry em waves.

so over a period of time if the electrons keep flowing away from an
antenna it should become positively charged.  and the longer it
operates the higher the charge.  unfortunately this is not the case,
antennas do not give off electrons any more than they have magical
levitating neutrinos like art prefers.

I can demonstrate that electrically charged items can repel each other.
I can demonstrate how magnets can repel each other.

How do I demonstrate the repelling effect of gravity?

My 40/80 (modified for extra bands) W9INN dipole is getting old and I need to replace the center connector. I am not sure what Bill W9INN used for the center connector but it looks like a W2AU 1:1 balun.

Can someone verify what Bill used and recommend a replacement.

Dick AA5VU

W9INN (SK) is missed!

Only can. Strong charged attracts the weaker charged.

> I can demonstrate how magnets can repel each other.

The same as above.

> How do I demonstrate the repelling effect of gravity?

An apple fall down but Moon dust levitates. Is it repelled?
Aepinus was sure about that. Now no doubts.

>no, i am not a student, i am an engineer by training and scientist by

title. where in maxwell's equations is there an aether?

Maxwell's equations are wrote by Heaviside (engineer).
Maxwell did the aether model and proper math.
Teachers often use big names to support his program teaching.
 The same is with Ampere. His name is used to support the magnetic whirl.
For Ampere the magnetism is an illusion. It is the electric field of moving charges.

>not all antennas have blunt tips, and electron's don't just 'jump off'
an antenna.

Whe they are? The reflected wave is weaker.

>no, just because there are electrons in space doesn't make that an
aether. there are electrons flowing in vacuum tubes, that is a
current, not an aether to carry em waves.

The same is in conductors. Currents are DC or AC. Maxwell's displacement current is the AC (oscillating).
In Maxwell's aether the current in the wire oscillate in phase with the displacement current in the aether.

Why are you the slave the only one hipothesis. The "like sound" is the theory.

In textbooks no statements which one is correct. The all are presented.

Is antena grounded?
All circuits are closed. The receiver antenna also do not become negatively
charged. The Earth closes the circuit.

>antennas do not give off electrons any more than they have magical
levitating neutrinos like art prefers.

I am using only old theories proved by experiments. Art is probably trying
to do the new.
The same was with Maxwell. He did the new. May be that Art's hipothesis the
teachers adopt to teaching.

Because of comments made I decided to abandon the idea of increasing the diameter of the dipole which really is a bit off the wall and decided instead to change frequency applied to obtain a low to near zero impedance. This approach did not result in a truly spherical radiation pattern and nor did it remove vortices ! The pattern when cut always revealed a figure 8 somewhere. Never the less, peak gain produced by the program always produced a larger volume pattern when impedance was a minimum. This certainly implies that because of the loss of skin the element impedance was lowered and thus the radiation would increase. Of course it depends on the observer to interprete observations where others may well differ.(A sure certainty in this group)

I am beginning to see an analogy between radiation elements and water, where water being diamagnetic would attract particles. Looking at it in radiating terms, the current would flow within the intersection point outside the water and propel the individual particles from or part of the skin which really is an encapsulation surface of a material other than water. Since mass inside the boundary does not change because of instant replacement the

boundary mathematical approach would still hold.
Of course, if the skin was actually made of particles
the addition of soap to the radiator surface would render it immune to
radiation if bubbles were not created thus leaving a diminishing
surface area of broken skin.Hopefully I have supplied enough material
to anger those who are sure they know all about radiation and thus
provoke them to finally declare exactly what is happening in a
scientific manner ala details, details,details
Regards
Art

Got delivery to-day.

As mentioned earlier, most of the stuff is old hat to me - but I really look
forward to dig into the chapters concerning tx output impedance. A highly
controversial subject for decades.

vy 73

only in very basic non-scientific treatments. this is getting old
again, it is obvious you have stuck a hundred years or more in the
past and will never catch up.

you really must chat with mr. b. now that you are talking about water
waves you are both on the same 'wavelength' so to speak.

antennas do now have to be grounded.  how are antennas on satellites
grounded??  do satellites become massive positive charges in space as
they keep shooting off electrons... again, this is going no where,
when you have read another hundred years of science and are ready to
believe what has been well proven over that time period maybe we can
have a conversation.

Is that a good example of what you call conversation?
 Waves and wavelength !!!
Talk with Mister B?
I would do that at a drop of the hat if the outcome was that you
wouldn't engage me in conversation for a hundred years as you promised
him.
I left you a clue with respect to water and the
collecting of Neutrinos but again I over estimated

your interlect
 I don't think I can go much lower, you as a person has already hit
rock bottom.
Hey a question for you. Richard lives alone, so does Kotar .Possibly
the other regular hacker also. Would I be correct that you also have
to live alone as you seem to fit the standard model of driving people
away?

Reminds me of a comment an engineer made to me in jest "We're making up shit as fast as we can!".

And that's about all that needs to be said about Art's latest journey into fairyland.

So desperation is setting in now.  He is grasping at straws about which
he has no knowledge.

Let's try a similar useless tactic!

Have you stopped beating your wife Art?

Tom I just can't see you holding your tongue or being civil for any
length of time! It is quite obvious that you have to live alone. Me? I
just celebrated my 50th anniversary with my wife. Monday we all
celebrate my daughters wedding anniversary where all the tribe will
appear. Another great evening on the horizon. Eat your heart out. And
yes, you called it right, your comment was a useless tactic.

Just as useless as yours, since you know nothing of what you speak about
myself and others.  That was my point.  Duh.

```

I just modeled two coils counter wound and one inside the other as a complete closed circuit , end fed. Counter winding is quite the norm with special purpose machinery to prevent inter tangling of coils when compressed.

With the coils wound opposite to each other
it made quite a nice antenna when placed on a flat plate. Beam was pencil shaped without side lobes and sensitive to all polarities.Thus any such dishes could be used for 'point to point' using any type circular polarization. Smaller in size compared to other designs is rather obvious. Where Kraus determined such an antenna single wound form demanded a certain angular pitch such a requirement is not apparent with this design. Kraus assumed a certain pitch was required when wave composition clashed, but the opposite happens when particles vectors add. Another example of particle versus waves disputes.It also confirms Maxwells equation by removing the effect of lumped loads which was not included in his equation as was not the stipulation that a radiator must be straight.

Caution:
Above details not yet "printed" in a book so it must be considered questionable.
Regards
Art

I imagine the beating of a wife would procede the sessation of the
above so you would know nothing about the latter until desertion came
about.
Some time ago I saw a man argueing with himself
which was the mirror image of himself as he looked outside. Is that
where you get your experience from
and your need to win at all times?

We had been settled on the name for about 2 months when her friend
told her it was the name of guitars.While it started as a joke I began
to like it. Daughter IS very much into music.Plays piano xylophone and
flute.

Jimmie

Is that how your ex wife characterised you after you challenged her
every day after day? I start a new thread in the hope of getting rid
of you. But when I talk antennas you turn to trash because you know
nothing else other than being a hate full and evil person . Read your
own past postings some time and characterise the person behind what
you read. Not very pleasing right!

Here is a simple little test for the hypothesis that Zs=50+j0 that uses equipment found in many if not most HF ham shacks.

"A wire that runs from the motor to the machine's frame to absorb stray
electric charge. Chassis ground is used when it is not possible to connect a
grounding conductor into the earth. "

" how are antennas on satellites
grounded??

To chassis. Your mobile phone also.

 >do satellites become massive positive charges in space as
they keep shooting off electrons...

They mainly transmit. So chassis is enough. Chassis must has the large area
to dissipate/absorb the electrons from space.

> again, this is going no where,
when you have read another hundred years of science and are ready to
believe what has been well proven over that time period maybe we can
have a conversation.

Take a glance at: http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
And tell us what is your opinion on Maxwell's model of the aether..

again, it is obvious you have stuck a hundred years or more in the
past and will never catch up.

Maxwell's model of aether (two substances) is from 1861.
Dirac model of aether (electrons see) is from 1930 (about).

Who of us is a hundred years or more in the past?
Who do not catch up?

argh, one wikipedia article and you are an expert.  good bye cruel
usenet, i have real antennas to work on... including the ferromagnetic
pointy ended non-grounded and yet uncharged ones that art can't
explain.  you guys enjoy your delusions.

I recall Simpson's Rule from work about 23 years ago that lead me to
finding more accurate methods in a great compendium of
     "Numerical Recipes
     The Art of Scientific Computing."
     Press, Flannery, Teukolsky, Vetterling,
     Cambridge University Press, 1986

which has Simpon's 3/8th Rule, and a more extensive
     "Bode's rule... This is exact for polynomials up to and
     including degree 5.
     "At this point the formulas stop being named
     after famous personages, so we will not go
     any further.  Consult Abramowitz and Stegun
     for aditional formulas in the sequence."
The book continues with FORTRAN (my first language) and Pascal (my 9th
or 11th language or dialect by that time) interpretations of a
spectrum of math systems for another 700 pages....

> Cambridge University Press, 1986

Honest, no name dropping here. In fact this citation neatly dove-tails with a film I just finished watching (god bless streaming Netflix) prior to this post that was about some of Cambridge's (and Oxford's, hence Oxbridge's) noted Dons: Cleese, Idle, Chapman, Palin, and Jones (with some Yank called Gilliam)
"Before the Flying Circus"

Some of these remarkable academics acknowledged, with gratitude, the groundbreaking work of Stanley Unwin - on par with the Goon Show.

Somehow all these loose ends tie together here - eventually. One has only to wait....

Lost on quite a few here I'd think. Who would know who Spike was? Or
what would become of Peter?

>
> Up to now light is not coherent. But in future who knows.

"As the electrons are undergoing acceleration they radiate electromagnetic
energy in their flight direction, and as they interact with the light
already emitted, photons along its line are emitted in phase, resulting in a
"laser-like" monocromatic and coherent beam. The mirrors show in the sketch
below are superfluous, as all the light is emitted in one direction anyway."
From: http://en.wikipedia.org/wiki/Halbach_array

So we have the light like the radio waves: Monocromatic and coherent. But it
is not from plain lasers.

"Sz Bialek wrote:
"Why the dipoles exhibit the directional pattern?".

John D. Ktaus wrote on page 3 of his 1950 efition of "Antennas": Fig. 1-3. a length chart for EM waves from the microscopic to the astronomic. Kraus was a famous radio astromoner. He obviously believed the EM Spectrum was continuous, so do I.

Terman begins his antenna section in his 1955 edition of "Electronic and Radio Engineering" on page 864. He explains and illustrates how vectors form and control the far field radiation pattern of antennas. Polarization is the direction of the electric field in the antenna and in the field produced by the antenna.

Dipoles have nulls at their ends and maxima perpendicular to the conductor as Terman shows in Fig. 23 on page 865,

Today, the postman felivered my eagerly awaited copy of W2DU`s "Reflections III" and I can`t wait to read it either.

Best regards, Richard Harrison, KB5WZI

nothing is perfect. even radio waves are not perfectly monochromatic
and hence not perfectly coherent either. but they are close enough
that we can tell they are the same phenomenon, they are all
electromagnetic waves and obey the same laws.

Art wrote:
"I just completed an experiment with my antenna optimizer program where I had a dipole in free space and where I increased the diameter until it was close to .003 ohms resistive. What this means is the current flow is right at the surface where there is no skin depth penetration involved and it is close to zero material resistance. This means the total resistance is the resistance of the surface encapsulating particles. The radiation was 35 db in a shape close to that of a sphere."

Ask yourself if the exerimental results are reasonable.

According to Terman:
"Radio waves are produced to some extent whenever a wire in open space carries a high-frequency current. The laws governing such radiation are obtained by using Maxwell`s equations to express the fields associated with the wire; when this is done there is found to be a component, termed the radiated field, having a strength that varies inversely with the distance."

The simple very short elemental dipole has a figure of eight pattern cross section and produces a power gain of 1.5 over an isotropic radiator, which produces the same radiation in all directions. 1.5 = about 2 db power gain as 3 db represents about 2X the power.

"Radiation close to that of a sphere" is close to isotropic or uniform in all directions, the standard for 0 db gain, not 35 db.

About the only asvantage of a fat or cylindrical dipole is broader bandwidth than a thin wire dipole which has the same gain, is cheaper, lighter, and has less wind loading.

One beautiful day if Art keeps trying he may have an original idea that works.

Best regards, Richard Harrison, KB5WZI

Nobody  know what the EM waves are. See what Maxwell wrote: "I propose now
to examine magnetic phenomena from a mecha nical point of view, and to
determine what tensions in, or motions of, a medium are capable of producing
the mechanical pheno mena observed. If, by the same hypothesis, we can
connect the phenomena of magnetic attraction with electromagnetic phe nomena
and with those of induced currents, we shall have found a theory which, if
not true, can only be proved to be erroneous by experiments which will
greatly enlarge our knowledge of this part of physics. " From:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

Our knowledge is enlarged enough to say:
Now we can tell that light. radio waves and sound are the same phenomenon
and obey the same laws.
S*

Electric field is along the wire. If antenna has the ball on the end the
electric field is at right angle to tha ball surface.

> Dipoles have nulls at their ends and maxima perpendicular to the
> conductor as Terman shows in Fig. 23 on page 865,

At the ends of the dipole the voltage is doubled (at least).

>
> Today, the postman felivered my eagerly awaited copy of W2DU`s
> "Reflections III" and I can`t wait to read it either.

In meantime read this: http://en.wikipedia.org/wiki/Standing_wave

In Maxwell's hypothesis the electricity is incompressible. Standing waves in antennas are the experimental prove that the hypothesis is erroneous.

See what Maxwell wrote: "I propose now
to examine magnetic phenomena from a mecha nical point of view, and to determine what tensions in, or motions of, a medium are capable of producing the mechanical pheno mena observed. If, by the same hypothesis, we can connect the phenomena of magnetic attraction with electromagnetic phe nomena and with those of induced currents, we shall have found a theory which, if not true, can only be proved to be erroneous by experiments which will greatly enlarge our knowledge of this part of physics. " From:
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force

In textbooks are prsented all theories and hipothesis.
It is your choose which one do you prefer: EM, photons or like sound.

The transmissing line is in open space.
It seems that radio waves are produced from ends of the wire where the
voltage is doubled (at least)

> The laws governing such radiation are
> obtained by using Maxwell`s equations to express the fields associated

Maxwell's equations (wrote by Heaviside) are for the incompressible
electricity. Such electricity create the oscillating magnetic whirl. Such
whirls are transwersal.
The Maxwell's hypothesis is erroneous.

> The simple very short elemental dipole has a figure of eight pattern

Half waves dipoles or shorter are always the two sources of waves. The
pattern is a rsult of interference of them.

The quantum electrodynamics process for the generation of EM waves is

well understood. The electron carriers in the wire are alternately
accelerated and decelerated by the transmit signal energy. During the
acceleration process, electrons absorb energy. During the deceleration
process, electrons emit photons, the quantum particles associated with
the radiated EM waves. Electrons at the ends of a wire dipole are not
accelerated as much as the electrons in the middle of the dipole.

> Ask yourself if the exerimental results are reasonable.

Why
Reasonable means no change from the deductions made in the past aka
resistance to change.

An experiment is an action which requires an explanation otherwise
there is no reason to do it.
I had no expectations of what the results would be that I would have
to provide an explanation for.

Superconductivity reduces resistance which could correlate with
removal of fields from that which the current is applied. If this is
correct I sq R suggests
increased radiation. This would appear reasonable
If the fields transferred to a nearby medium whether it be a

encapsulating material or just a nearby substance one has transfered
the problem
to one where the fields in a adjacent material is handled and where
the applied power is applied to a member without resistance.
Is that reasonable ? Yes it is. Explanable is another question. This
is the very reason for any experiment
with respect to education. Reasonable means that
it does not meet expectations which, if we are not willing to think
about, means discoveries are impossible.
First question to ask is superconductivity a reality ?
Second is whether antenna programs are to be trusted?
I did the experiment with purchased material and it gave me the above
results which I am sharing.
So the question becomes is it correct and why is it not correct. First
thing to look at obviously is can a field or fields be removed from a
conductor?
In boundary laws if we don't consider the passage
of static particles that enter the boundary compared to those that
leave the boundary then things become awkward because we also know
that we are taking account of flux transitions.
If Gaussian laws state that static particles can become dynamic then
the answer is that fields can
exist beyond the sphere to which current is applied.
Now that is my personal suggested interpretation of what happens to
provide agreement with the experiment findings. Other interpretations
provided could appear more valid.
I am not equipped to comment on the validity of the computer programs
as Maxwells equations do not explicitly explain the mechanics of
radiation so I leave it to others to provide better answers for the
situation seen above. Yes, I know that the interpretation of Maxwell
is not fully supplied in the books so I invite others to advance
suitable explanations. Is that so bad?

It was a few weeks ago.
Electrons are decelerated at the ands of the dipole.
Next they accelerate and in the middle (of the oryginal Hertz dipole) the
speed of electrons is constant (no acceleration/deceleration).

In textbooks are prsented all theories and hipothesis.
It is your choose which one do you prefer: EM, photons, QED or like sound.

"QED mathematically describes all phenomena involving electrically charged
particles interacting by means of exchange of photons".

QED is about Photons, not EM waves. Photons have the analogy in phonons. So
radio waves are like the sound.

On May 19, 2:03=A0pm, "Szczepan Bialek" <sz.bia...@wp.pl> wrote:

> QED is about Photons, not EM waves.

From "QED", by Feynman: "So now, I present to you the three basic
actions,
from which all the phenomena of light (EM waves) and electrons arise.

-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

Photons and EM waves are the same quantized phenomena, viewed in

different mathematical ways. A single photon can pass through two
slots
at the same time and interfere with itself on the other side.

Dick,
Just click on this link it will give you quite a few options for obtaining a replacement.

Extra information

When resonant at 50 ohms resistive the donut shape was evident and provided by two vortices.

As the resonant value dropped so did the depth of the two vortices

At 5 ohms resistive the vortice depth really started to reduce in depth.In other words as the vortice reduced so did the skin depth and where the reduction in vortice volume was taken up by radiation. When the resonant point was brought to a fraction of an ohm the vortices had virtually disappeared and the radiation increased such that the total radiation became a sphere which equated to a maximum radiation value. Dropping the resonant value below zero ohms removed the radiation pattern from its normal progression.

This would infer that zero displacement current was generated which means that particles were only elevated and not projected or accelerated in any particular direction which thus permits a sphere of radiation, contrary to that where particles were accelerated in any particular direction. Note that it is the intersection of two fields that created acceleration and direction as shown on my antenna page and with direction the donut shape is retained. Thus this line of logic supports the idea of a spherical radiation pattern as, with the absence of resistance so goes the absence of eddy or displacement current.

Wow! I'd really like to see this vortex, sorry these vortices, that you
have produced.

Is the rotation right or left handed?

This is REALLY COOL!

Please post the file and which optimizer software that you are using.

Thanks!

tom

The presence of these vortices are used to determine imperfections in materials during manufacturing processes. Removing the presence of such is the primary reason for laminations instead of solids in the manufacture of transformers.I am surprised that you are not familiar with the concept of skin depth when at the same time you consider yourself as an expert with respect to antennas. The antenna program I use is
AO Pro purely because it has an optimizer to ensure Maxwell's equations are adhered to as well as accountability for all vectors involved. Planar devices are quite efficient such as the Yagi but planar devices are not in equilibrium which is a requirement of Maxwell's equations! I imagine that with any program you could fiddle with a dipole
construction such that it was resonant at a very low impedance to obtain a progression for radiation
pattern /volume versus impedance if it does not posses optimization abilities. The free EZNEC program probably will be good enough.
As far as vortices are concerned the same two vectors used with antennas are also evident with the Earth's weather system. For instance, a tornado
or a whirlpool presents a vortice by virtue of the intersection of two vectors involved. Remove one intersecting vector and the vortice disappears. This is an example of what Einstein saw with respect to his leanings on the unified theory.

I was in the US Navy from 1962 to 1982 and encountered the venerable
R-390A receiver on many occasions.  By design, the -390 was equipped
for diversity if you manipulated some straps on the rear panel.
However, the one time that I tried to use a pair of -390s in diversity
mode the results were less than spectacular.  I was on a ship and we
copied an RTTY broadcast that was being keyed on several frequencies,
all subject to QSB.  I suspect that the combined audio signal, even
though it sounded better (less apparent QSB), was degraded by
differing path lengths for the two signals, causing timing jitter on
the recovered TTY signal.   Whatever the reason, performance was
worse, not better.

Our baby name generator wizard can help you find some unique names for
your new bundle of joy!  Just click on either button below (depending
on whether you are looking for a baby boy or baby girl name) or our
wizard will suggest a name for you.  Push the button as many times as
you want until you find the perfect baby name you love!

different mathematical ways. A single photon can pass through two
slots at the same time and interfere with itself on the other side.

I wrote: "In textbooks are prsented all theories and hipothesis.
It is your choose which one do you prefer: EM, photons, QED or like sound."

So you prefer the all.
The "like sound" is the oldest and explain the all phenomena.
The new ones: EM, photons, QED explain only some. They are the fantastic
pieces to teach.

My W9INN dipole does not use the W9INN Balun Box.  It uses something
made by Bill that looks like an MFJ-918.

Check from the coax connector to each side. I just did this with a Spi-Ro
160 I have been using.
Center to the end of one side was a complete closed circuit. The other side
shield to end was open. From the connector to the coil was closed but nada
on the other side of the coil. So in my case the coil is bad.

To start all you need to test is from the coax connector to each side just
beyond the center connector/balun. W9INN used a 1 to 1 balun
along with a connector. You can used a budwing
center connector then add the balun (2 pieces).
I would suspect the balun first then the center connector. If that antenna
has traps check them also if everything is Ok in the center.

Good luck.

mr. b. you and art should get together. i'm sure his vortices off the
ends of his over optimized dipole would work well with your sound
model of electromagnetics. he has forced the particles off the dipole
by making it superconductive so they should respond like perfectly
compressible sound carriers and since they are massless the sound will
travel at the speed of light. how perfect could that be! both new
theories come together in one big never ending thread where we can all
read the bafflegab and have a big laugh behind your backs, or maybe
right in your faces. Sorry i've been a bit slow responding, i had a
nice trip to dayton, but didn't find any of the unwin antennas for
sale, or any sound driven dipoles out in the flea market either...
well, maybe next year, i'm sure you'll both be selling those new
superconductive longitudinal wave generating magical levitating
diamagnetic neutrino hyperwave antennas at bargain basement prices
after everyone learns how bad they really are.

Dave K4JRB,

I suspect one of the two is open inside the closed PCV. Going to drop
it tomorrow to run the test.

In article <ifydnZ9hSuOuKGjWnZ2dnUVZ_smdnZ2d@earthlink.com>,
 "David Thompson" <thompson@mindspring.com> wrote:

Oh that's right, I forgot. You use my god child. I asked Brian to do that program for 2 or 3 years before he finally did. I was the alpha tester on it and other of his programs.

You do know that's just MiniNEC, right? With all the problems MiniNEC has included for your computing pleasure.

It's off frequency - low. And it gets worse as the wire diameter INCREASES. Which is what you are doing in your example.

It also doesn't like bent wires, as in things that don't meet at 180 degrees. It breaks down completely at less than 28 degrees.

It doesn't like adjacent segments that are in a ratio greater than 2 to 1.

And it doesn't like adjacent wires that are closer than .23 of a segment length.

Given some of the things you have posted that you have modeled, I'd guess that you break a minimum of 1, normally 2, and sometimes 3 of the above conditions.

No wonder your stuff acts abnormal.

And you are using this tool to attempt to prove your twisted theories about Maxwell's equations? That's like using a chain saw to do brain surgery.

tom

All very interesting Tom but frankly you lack credibility. As with
other posts of yours you do not provide specifics and more than often
express opinions. I personally am as pleased as punch in what I
purchased from Brian and I certainly do not believe he would foist on
the ham community anything but his best. Knowing that he is not
exactly a peoples person I suspect he would not shy from a clash with
you when you distribute your personal opinions. So I can imagine why
such a person like you would jump at the chance to savage another's
personality. For my part I use the program strictly for his adherence
to Maxwell's equations which is the approach that I take. This allows
for an over check most times when ensuring
that arrays proffered meet the condition of equilibrium of each part
and all of the provided
array. I doubt very much you would have strayed beyond the Yagi and
other planar designs when testing, but then you are not short of
claiming anything that may boost your position in life.
Thanks for your operative points offered and I will certainly consider
them within the specific technical confines which you so gently
provided.
Regards
Art

It was his best, but based on MiniNEC. He couldn't change that. He did
tweak things in YO because it was special purpose, but I believe he left
the engine in AO pretty much alone.

> exactly a peoples person I suspect he would not shy from a clash with

> for an over check most times when ensuring

It adheres to MiniNEC's core. Which adhere to Maxwell no more and no less than that. And it has serious and known shortcomings, which you seem to want to wish away. Brian did a great, hell spectacular, job with what he started with, but he couldn't make the problems with MiniNEC disappear. No one has done anything like it that is available at the prices he charged since then. But the user needs to understand the limitations of the product.

> that arrays proffered meet the condition of equilibrium of each part
> and all of the provided

AO knows nothing of the equilibrium of which you speak.

> array. I doubt very much you would have strayed beyond the Yagi and
> other planar designs when testing, but then you are not short of
> claiming anything that may boost your position in life.

You have no idea what I have done, designed or built. But I would bet I've built more, and that it works better than anything you have come up with unless you copied it from someone else.

And this comment from someone who never states anything about his
miracle antennas except the fact that they are miraculous.

Yes, you are Mr. Credibility!

Tom I try to provide the specifics with respect to my posts because without them there can be no discussion. I do get discussions and generally they are not as nice as I would like them to be but others do get involved while at the same time providing worth while comments such as the continuity of the donut shape which forced me to reconsider. As far as minninec is concerned I had no other choice since I required an optimiser but even so minninec surely has its problems the same as NEC. If and when NEC tries the optimiser aproach I suspect they will incorporate minninec in some way. As far as the faults you pointed to I can't imagine not placing segment opposite each other for close spaced elements or in fact placing much confidence in bent angles in the area below 30 degrees whether it be eznec or minninec.

When I started to look away from yagi's and planar devices I followed the standard rules of mathematics with respect to equilibrium and Maxwell's rules, I was very pleased that the mininec conformed to my expectations. This however, did not stop me from getting confirmation else where using NEC4. So again I have no reason not to trust AO any time before I distrust myself when I am more than willing to declare what I did and who I am. The reason I do respond to your posts is to encourage you to use free speech and thus force you to disclose what sort of person you are to other members of the group, and not for its technical content. I have on my page unwinantennas a sample of an array (diversity array)that conforms to my thinking with respect to

Maxwells equations
which were fully revealed to me by the expansion of
Gauss theorem from static to dynamic in every way,
which provided the evidence of particles as the carrier of radiation.
Since nobody on this group is willing to understand the meanings of
equilibrium in physics or the legitamacy of changing static parameters
to dynamic, minninec did supply the backing for my thoughts in every
way which no other program that was available was capable of.
Have a happy day
Art

And yet you never, ever, give numbers that define your antennas,
excepting the almost planar example antenna. Which doesn't work all
that well, actually.

You have to present some examples of things that actually work well
before you are considered credible.

And given your claims, you are expected to show antennas that are
demonstrably better than current designs.

So far you have not done any of the above.

I am going to build an array of 4 stacked dipoles for operation on 2 metres.
I would like to know whether the gamma fed dipole has any advantage over the
folded dipole, apart from the folded dipole being a tad more difficult to
make.

I have heard that the gamma fed dipole has a skewed radiation pattern in
comparison to the folded one.

Any thoughts and advice?
Many thanks
John

Hi John,

You could have heard the same thing said for the opposite design - and
they would BOTH be true.

The devil is in the details, such as how much skew would it take to
bother you? Then there is the question, how much skew before it would
it matter anyway? Some folks sweat over things they couldn't possibly
measure. Worse yet, they would pay more to change things than they
would get back in improvement.

>mr. b. you and art should get together. i'm sure his vortices off the
ends of his over optimized dipole would work well with your sound
model of electromagnetics.

Sound model of electric waves is the oldest (XIX century). I am not young
but it is not mine.

> he has forced the particles off the dipole
by making it superconductive so they should respond like perfectly
compressible sound carriers and since they are massless the sound will
travel at the speed of light. how perfect could that be! both new
theories

May be that the Art's is a new. The "like sound" is the oldest.

>come together in one big never ending thread where we can all
read the bafflegab and have a big laugh behind your backs, or maybe
right in your faces. Sorry i've been a bit slow responding, i had a
nice trip to dayton, but didn't find any of the unwin antennas for
sale, or any sound driven dipoles out in the flea market either...

All dipoles are with the standing waves (like sound).

>well, maybe next year, i'm sure you'll both be selling those new
superconductive longitudinal wave generating magical levitating
diamagnetic neutrino hyperwave antennas at bargain basement prices
after everyone learns how bad they really are.

"Like sound " antennas are in sale for ages.
If Art's are or will be - I do not know. I am not an expert. (I have trouble
with understanding Art's idea - he is using very sophistcated terms).

The Chronicles of Arthur Unwin. :/
Delusions of grandeur induced by abuse and misuse of
antenna modeling programs.
Excessive adult beverage consumption may also be

an issue, but I couldn't really say being as I can't give
him a breathalyzer test over the internet...

Heck, I think more than a few of the common programs
have "optimization" routines. Big deal.
I know the freeware MMANA does..
And having played with it a bit, I know you have to take
the results with a grain of salt, and often the results were
worse than what I would come up with manually. :(

Say optimizing a yagi.. I've seen some fairly peculiar
and below par results using the optimization in that
program. Art's blind trust is rather peculiar. :/

Not to mention some of his peculiar theories and notions.
IE: if the pattern of an antenna displays an isotropic
pattern, how in the heck are you going to have large
amounts of gain? The gain would be near zero if using
isotropic antenna as the reference.
Not 32 dbi or whatever number he came up with.
In order to have gain in any direction, a null must form
in some other direction. No free lunch. Sorry.
Of course, Art seems to confuse efficiency and gain, but
that's a chapter for another day.

Art generally ignores efficiency. In his world, equilibrium,
neutrinos, and solar fairy dust particles with levitating vortex
swirls cause efficiency issues to vanish into thin air.
If the vortex swirls start to resemble what you would see
off a Boeing 757 on a moist cloudy day, you have total
equilibrium and obvious 100% efficiency and 87 dbi gain
in all directions.
Tell Jethro to fix the brakes on the truck. We may be moving
soon. :)

Say as when using an A/C fan motors worth of thin wire wound
on a short stick of PVC and supposedly operated on 160m.. :(
But even Art himself claims to almost never actually use the
transmitter in his rig. Being as even a stick of wound wire can
receive halfway well on the low bands, we have a new miracle!
Never mind that some guy tried the same thing about 85 years
ago I'm sure.. :/ It doesn't work any better now than it did then.
Back to the drawing board for prior Art..

No transmit tests or comparison with known benchmarks are
required in the world of Art. The masters sayeth, so it must
be true! Woe to the non believers! They knoweth not what
they do or say!

They have no equilibrium!

Call the patent office, and get the lawyers on the phone!
Load up the truck, we're moving to Beverly Hills. :)

Did Jethro ever fix the brakes?

In the dark recesses of Art's brain, he applied the theory of
reciprocity to this antenna. It receives fairly well, so it surely
must transmit in a like manner.
If only the world were fair.

Next week.. If you run over a neutrino with a Goodyear
Accutread tire, will a puncture occur?
The answer to this question and many others on the next
installment of Art's Chronicles.

"All phenomena", including traveling at the speed of light in a
vacuum? :-)

All without exceptions.
In the space are free electrons (plasma). If you move one of them the next
reacts on it. It is normal pressure wave (electric wave).

It is intresting that the speed of electric waves are the same in vacuum and
in conductors.
In insulators the electric waves travel slower.

Richard Harrison has posted a number of times the comment that systems using folded dipoles are much more robust with respect to lightning and static discharges due to the low impedance path for DC and most of the RF components they contain.

Yep.

As I point out when I give a talk about antenna basics, the isotropic radiator has the lowest possible gain for any lossless antenna, if you consider an antenna's "gain" to be its gain in its best direction. In other words, any lossless antenna has more than 0 dBi gain in some direction.

I make sure I point this out before I introduce very short and theoretically lossless dipoles. A free space dipole has a gain in its best direction of about 2.15 dBi. No lossless antenna can have a gain in its best direction of less than 0 dBi. So what should we expect the gain of a very short dipole to be if we could make one with no (resistive) loss?

As given, the average gain is about 16.7 dB - so one knows that something-is-afoot . . .
The driven element (wire 1) is essentially touching wire 4. Current in wire 4 is unbelievably high. With use of #30 wire things improve, but wires are too close.

Thanks for the example. Will use it when next talking about NEC as an example of what not to do.

maxwell's equations are ALWAYS exact, it is digital models that are
inexact and have limitations due to the approximations made and the

numeric representations used.

Hi Tony and Jim

I think that it was not a crazy thing :>) A rapid simulation of a
full size three element 20 m Yagi in 4NEC2 software gives me aprox. 32
+ j0 ohm with a length of 5.12 m per excited element leg, lengthen to
5,37 m, impedance raises to 37,4 + j51,5 ohm, it is not so much as 50
vs 30 ohm for 50 ohm inductive reactance augment claimed for Mosley
guys but if we add some possible losses perhaps that approach was
valid enough for them (I should verify more carefully a more real
model with loading coils, etc)

I tried the EZ-NEC file representing a 50-MHz three-element NBS Yagi.

At resonance (49.95 MHz) impedance is 12.05 + j0

Lengthening the radiating element by about three inches causes impedance to become 14.34 + j50

To show 50-ohm resistance, the antenna losses should cause the birth of a (50-14.34) = 35.66 series resistance. This would cause a loss of about 5.4 dB, so nearly offsetting the antenna gain.

73

Interestingly, MININEC uses the very same method of moments that NEC does, but, because it's "mini" it has substantial limitations. It was developed to fit in small microcomputers of the day. I'd hardly call NEC "patchwork". The two programs do use different formulations for the basis function defining the current on the segment.

There are several papers out there that compare the mechanism of MININEC vs NEC. One might start with the report by Burke and Poggio (for NEC) and the report by Julian, Logam, and Rockway (which talks about MININEC). John Rockway published a paper in 1995 describing the history and differences.

I personaly am extremely happy with AO since I am able always to do an
overcheck with respect
the element resonance. I wouldn't be surprised if the next generation
moved away from the present
algerithms and rely purely on number crunching to obtain systems in
equilibrium. I personaly believe
that the programs would be much more accurate if they had a better
understanding of close elements because of proximetry effects. But as
long as the industry strays away from non planar forms we will have to

live with close approximations. Tho using Maxwell to its limits I have yet to find a way to concentrate radiation for gain as opposed to efficiency by the introduction of other elements but I enjoy trying different methods and there is always a new vista that appears with its use. My next aproach will be a multiplicity of cells or boundaries dependent on how far my program can spread. One thing I am absolutely sure now is that particles are the staple of propagation where the neutrino act as the carrier and can well be the singular particle that Einstein envisaged based on the Earths two vectors.I was absolutely over joyed when AO allowed the radiating elements to gyrate towards zero resistance so that the encapsulating cylinder could be divorced from element thus removing losses. I see no better proof of my aproach in making Gaussian static fields dynamic
which clearly exposes the presence of encapsulation that is substantiated by the math and allows propagation to be viewed as a point source. Next time one visits the moon they can apply a time varying current to the space suit to prevent the carrage of particles to the inside of the ship.

On this I have total agreement. The moment one strays from the concept
of equilibrium is when we expose ourselves to errors.

24 % increment in 20 m example, 19 % in 6 m example. OK, Similar
numbers...

But don't forget that feedeing point impedance not always is near 10
ohms, Yagi feedeing point impedance typically takes values from 40 to
10 ohms depending on spacing, element length, coil loading, etc.

I think: If your assumed numbers were those of the Mosley beam, its
SWR would be 4:1(without losses), and with losses included she would
be =A1a very nasty antenna!. I think the ham buyers would not be very
happy with such a poor antenna on both cases :>)

I've found it in my best interest to check the consistency of results
in various ways, whenever I can. Often there's more than one way to
think about a problem, and if the answers I get differ, I want to know
why. Until I can resolve the differences, I distrust both (or all...)
answers. I also like to have an idea about the tolerance on the
answers, and many programs (and formulas you use to calculate answers
for yourself) don't give much of a clue about the tolerance. Some are
"exact," and some should be considered only approximations, but often
they don't bother to tell you which. One example is formulas for
calculating the impedance of TEM transmission lines; it's common to
see, for air-dielectric two-wire line, Z0=3D276*log10(2D/d), but this is
an approximation whose error becomes significant as d approaches D.
Even the better formula, Z0=3D120invcosh(D/d), is not exact: the 120
isn't exactly correct, there's no consideration of finite conductor
resistance (and resulting skin depth), and there's no consideration of
the atmospheric pressure and relative humidity...

I mostly agree with Tom: don't expect the program, or formula, to
know how you are going to misapply it. Try to be aware of what the
answers you get imply. Learn the limits of your tools (programs;

formulas), and apply them wisely so they will serve you well.

Do I get stung by my own foolishness in not paying proper attention to
things like this? You bet I do! Just last night, I entered a coil
into the Hamwaves inductance calculator and it was happy to give me an
answer. The coil? Ten turns of 1mm wire in a coil 10mm diameter and
10mm long... Duh, that's a 1mm winding pitch and the turns will short
together. I didn't think to check that at first. The calculator
complains and won't give you an answer if the pitch is less than the
wire diameter, but not if it's just equal. Considering the same very
useful inductance calculator, I've learned to ignore the answer for
the effective shunt stray capacitance: it in general doesn't come
close to matching the value calculated from the self-resonance and the
inductance. To see what I mean, try entering D=3D10mm, N=3D10, len.=3D20mm=
,
d=3D1mm, and check what C(L,p) is reported. Now try changing D in 1mm
increments up and down. OK, so I don't trust the reported C(L,p)
value, but because I've checked several cases of all the other
reported values against measurements of actual coils and against one
or two other programs I use, I've learned to trust those other
reported values, within some tolerance (that's a lot looser than the
reported precision in the calculator!). -- I don't mean to pick on
that inductance calculator, just to use it to illustrate what applies
to pretty much all calculation programs and formulas.

Cheers,
Tom

OK, it also helps to RTFM. The text down below the inductance calculator explains about this some. Also, I should have said that you need to set the "design frequency" to something low (e.g. 10MHz) to see the effect. However, the text suggests that C(L,p) value would be larger than expected...and I've also seen it for some coils to be considerably smaller. So I end up, then, not finding the lumped model including C(L,p) being very useful for the things I do, where I want a model that gives me _decent_ agreement over a broader frequency range, rather than perhaps more exact agreement over a very limited frequency range (as happens when the reported value of C(L,p) gets very large; try "design frequency" =3D 1MHz for that coil).

Cheers,
Tom

Remember, I have always specified that one does not go beyond the
units supplied by Maxwell, Maxwell did not use lumped loads. It is
stipulated
that equilibrium is paramount as soon as you see the "=3D" sign. Thus I
can say I am persueing exactnes or accuracy and not fudging.It was
when Maxwell followed the edict of the "equal" sign that he was forced
to add the particle elevation vector by the addition of displacement
current even tho
he could not describe the addition. To him it was a mathematical
```

equation and nothing else and without explanation of the process.

ok, so you DO agree that maxwell's equations that make no mention of
particles like neutrinos, gravity, coriolis forces, or levitation ARE
correct!  And therefor you must agree that the representation of
gauss's law encapsulated in maxwell's equations, WITHOUT an explicit t
in it must be correct!  You must also be admitting that your
optimization experiments are full of errors.  wow, now its time to go
and rejoice, art has finally come around to the real world!

Again I state. If you are using Maxwell equations you cannot stray
from the units supplied.Hams do not follow the rules with respect
to antennas so approximations are literally garranteed.
Using Maxwells equations alone you have the presence of point
radiation. With a single point radiation the rules of physics state
that radiation limits is in the form of a sphere. If one states you
cannot have a sphere of radiation they are breaking all the laws of
physics and I certainly had no part in the making of the rules.

you can have a spherically symetric static electric field as is easily
shown by gauss's law.  but in order to have 'radiation' (implying em
wave propagating through space) you must have movement of some kind,
that immediately removes the spherical symetry by creating an axis
defined by the direction of movement.  this is why even the
theoretical infinitesimal dipole still produces a doughnut shaped
field in free space.

Maybe this is good.. I have noticed my antennas tend to actually
work as radiators of RF, where as most of yours seem to prefer
to turn it to heat. :/  I think Maxwell must be taking you for a big
ride. I bet he's up there is the land of the big RF just laughing his
head off at all this silly jibber jabber you keep blaming him for.

How many cases of a single point of radiation have you seen
in the real world, using real world antennas? This is not a trick
question.

Miguel,

I browsed your reference.

The text following "MOSLEY TRAP MASTER AND POWER MASTER SERIES... A Discussion of Beam Antenna Feed Systems" is typical BS that comes from antenna manufacturers with more interest in taking your money than an understanding of how things work.

For example, the justification of unbalanced feed of the split dipole is sheer technical nonsense.

but as dilbert's trolls know, numbers create reality, not the other
way around. if you can't describe it in a formula, it can't exist.
and yes, while the current moves longitudinally along the wire, the
fields are transverse. look at the formulas, they apply to the wire
also. they just get more complex because you have to take into
account the boundry conditions at the interface between the wire and
what is around it... something that freshman physics and calculus are
not enough to handle.

Yep, one of its claims to fame is that it passes all the geometry and
segmentation checks that EZNEC runs. However, it does violate the
"spacing of elements" admonition in the manual.

I read on their web page for some more BS.

In explaining why their traps are lossless:

"Gain is a function of element spacing and boom length and not what
constitutes an element.  The published gain figures for our products are
dBd, actual measured gain.  Antennas which use other forms of trapping such
as linear loading, poor trap copies, baluns or matching devices have
inherit loss. "
```

So, all these things have inherent loss, but not their traps.

Fact is that GAIN is reduced by LOSS, anywhere and everywhere in the system, dB for dB. This includes conductor losses, dielectric losses, and trap losses which they exclude from their definition.

Owen

As I said: "I wanted to discover what was the supporting idea behind
that
feeding system for its designers"

Defend commercial stuff and his claims It is not my job (I do not
trust enough in all of them), I am an Amateur :>) but seems to me that
their concept it is not opposed to my modest theoretical knowledge
neither my simulations exercises in 4NEC2 (their "numbers" partially
agree with mine, although I have not simulated exactly a Mosley
antenna model).
Now I am only interested in validate or negate the especific technical
concept and explanation given, from a scientific perspective.

Proposition =3D>. Is it possible match the impedance of some Yagi
antennas lengthening the driven element and canceling its inductive
reactance splitting the element and adding series caps?
Can be made these caps with special pieces of insulated wire
introduced in element tube?.

Try it... lenghten in a NEC simulation the driven element and cancel
inductive reactance =3D> impedance raises and gain stays (I used
"3YAGI20.NEC" from 4NEC2 examples provided with Arie soft, for
testing).
In my test, raisen length from 5.12 m to 5.85 m per leg, Zin raises
from 31.8 + j2 ohm to 50.9 + j150 ohm and gain stays in 12 dBi (with a
fast ground and 15 m height).

That's a very clever qualitative explanation of, for, instance, why
isotropic antennas cannot exist. (without resorting to things like the
Hairy Ball Theorem, which is great for explaining polarization)

Ok, since you are discussing impedance matching, what was the effect on VSWR bandwidth.

It seems to me that as you go lower in frequency, the inductive reactance at the feedpoint becomes less and the series stub reactance becomes greater, so one aggravates the other.

The question is whether the outcome is narrower than desired or available with other matches.

Because Mosely's explanation contains so much BS, I have no faith in anything they have said.

Owen

A worthy goal.. There's countless schemes for feeding, most developed empirically, and all probably work about the same, but have some aspect that is convenient for manufacture, installation, patent avoidance; and a lot of them are just marketing sizzle (Now! with brigher color paint!

our patented 10 mm bolt with 1.618 mm threads in the Golden Ratio is available exclusively on our Whiz-Bang model 32 antenna! Worked all 5 boroughs of NY from the top of the Empire State Building on 40m!, etc.)

Running that model in free space gives a forward gain of 8.13dBi and a f/b of about 26.5 dB, with a couple of sidelobes at 115 degrees off boresight at about 29 dB down.

making the change you give, changes the forward gain to 8.11 dBi (insignificantly different), but the rear lobes get bigger: The side lobe is now 25 dB down (instead of 29), and the back lobe is at 24dB down.

Still not a bad F/B, though.

>

Changing the length of the elements changes the relative phases and magnitudes of the currents in the elements. You can have pretty big changes without affecting gain very much.

However, what *will* go bad in a hurry is front/back or sidelobe performance. The "cancellation" of the back and side lobes depends on the phasing of the currents.

So, if the goal is "reasonable gain" in the forward direction and "easy to build a matching network for" that's a valid strategy.

Just for grins, here are the currents in the center of each element:
